2.57	Unit testing	444
2.58	API Indice	448
2.59	License	882
3	Other formats	885

Welcome to Phalcon framework. Our mission is to give you an advanced tool for developing the faster web sites and applications with PHP.

What is Phalcon?

Phalcon is an open source, full stack framework for PHP written as a C-extension, optimized for high performance. You don't need to learn or use the C language, since the functionality is exposed as PHP classes ready for you to use. Phalcon also is loosely coupled, allowing you to use its objects as glue components based on the needs of your application.

Phalcon is not only about performance, our goal is to make it robust, rich in features and easy to use!

Table of Contents

2.1 Installation

PHP extensions require a slightly different installation method to a traditional php-based library or framework. You can either download a binary package for the system of your choice or build it from the sources.

2.1.1 Windows

To use phalcon on Windows you can [download](#) a DLL library. Edit your php.ini file and then append at the end:

```
extension=php_phalcon.dll
```

Restart your webserver.

The following screencast is a step-by-step guide to install Phalcon on Windows:

If you don't know what DLL to download, use the following [script](#) to figure it out.

Related Guides

Installation on XAMPP

[XAMPP](#) is an easy to install Apache distribution containing MySQL, PHP and Perl. Once you download XAMPP, all you have to do is extract it and start using it. Below are detailed instructions on how to install Phalcon on XAMPP for Windows. Using the latest XAMPP version is highly recommended.

Download the right version of Phalcon XAMPP is always releasing 32 bit versions of Apache and PHP. You will need to download the x86 version of Phalcon for Windows from the download section.

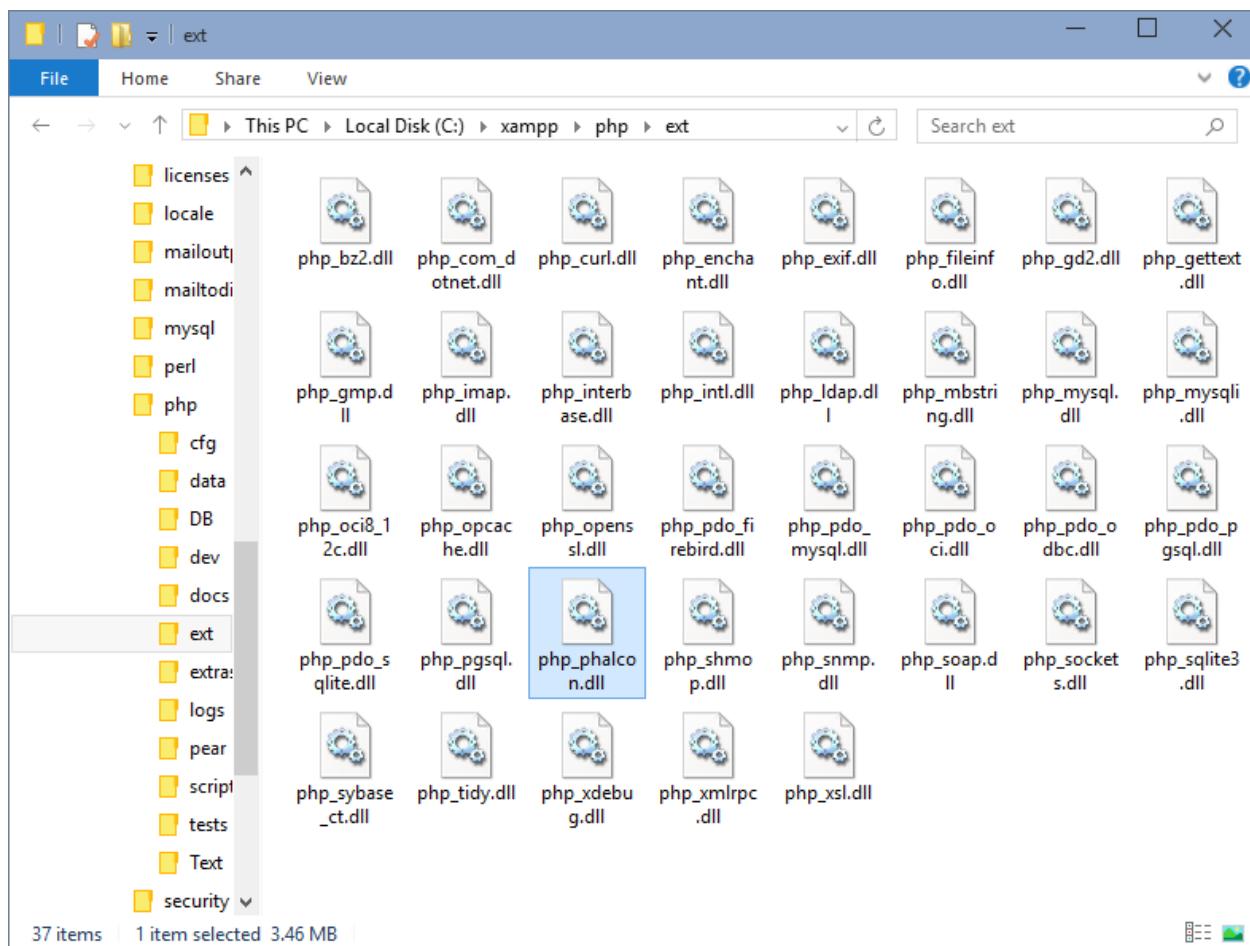

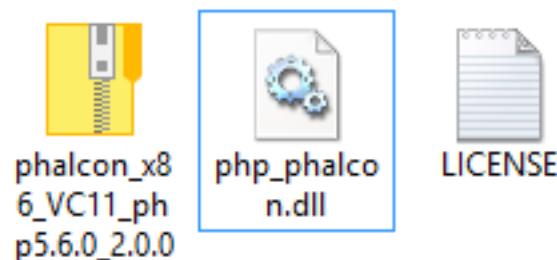

After downloading the Phalcon library you will have a zip file like the one shown below:

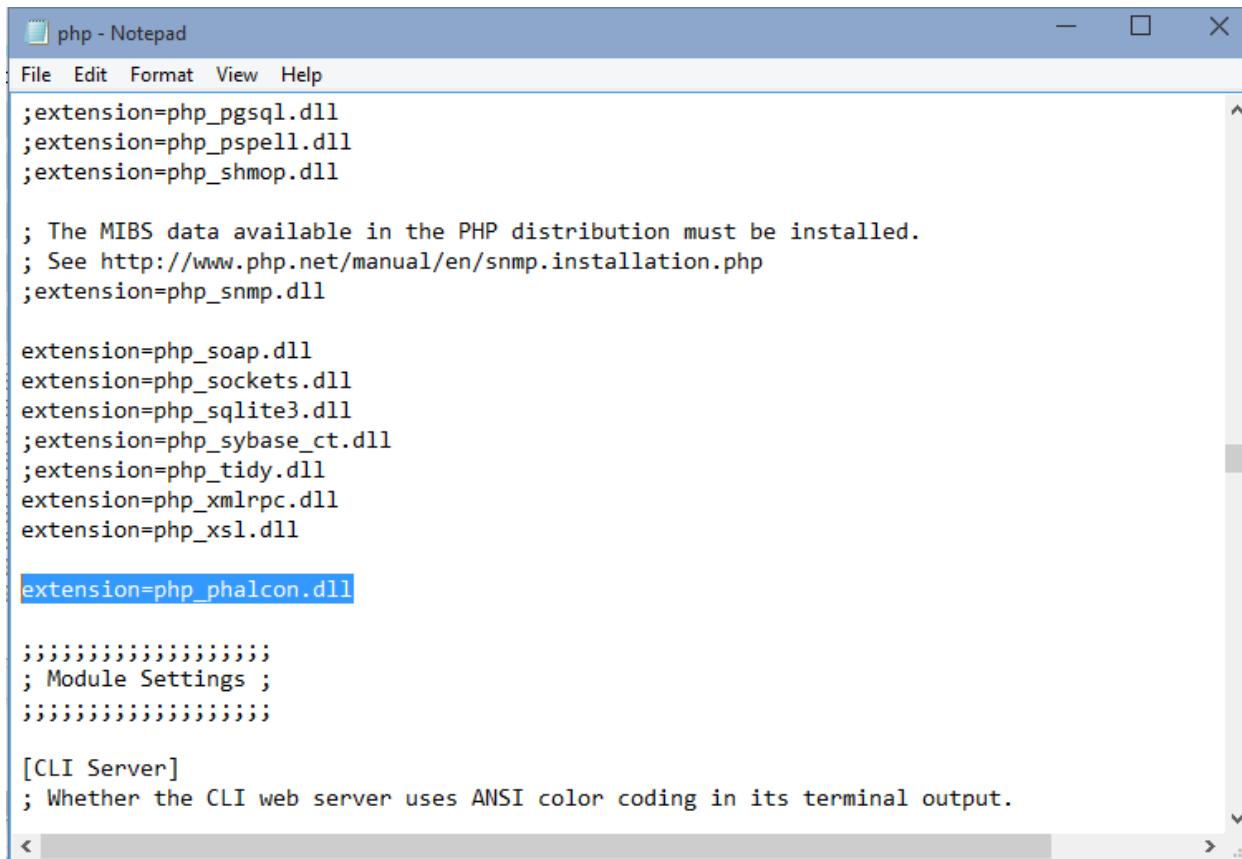

Extract the library from the archive to get the Phalcon DLL:

Copy the file `php_phalcon.dll` to the PHP extensions. If you have installed XAMPP in the `c:\xampp\php\ext` folder, the extension needs to be in `c:\xampp\php\ext`

Edit the `php.ini` file, it is located at `C:\xampp\php\php.ini`. It can be edited with Notepad or a similar program. We recommend Notepad++ to avoid issues with line endings. Append at the end of the file: `extension=php_phalcon.dll` and save it.

Restart the Apache Web Server from the XAMPP Control Center. This will load the new PHP configuration.

The screenshot shows a Windows Notepad window titled "php - Notepad". The content of the file is the PHP configuration file (php.ini). It includes several extension entries, a section for CLI server settings, and a log of recent events at the bottom.

```

File Edit Format View Help
;extension=php_pgsql.dll
;extension=php_pspell.dll
;extension=php_shmop.dll

; The MIBS data available in the PHP distribution must be installed.

[CLI Server]
; Whether the CLI web server uses ANSI color coding in its terminal output.

< > ...

```

Open your browser to navigate to <http://localhost>. The XAMPP welcome page will appear. Click on the link `phpinfo()`.

The screenshot shows a Microsoft Edge browser window with the title bar "XAMPP 5.6.3". The address bar shows "localhost/xampp/index.php". The main content area displays the XAMPP for Windows welcome page. On the left, there is a sidebar with links for XAMPP 5.6.3, Welcome, Status, Security, Documentation, Components, Applications, PHP (with "phpinfo()", CD Collection, Biorhythm, Instant Art, Phone Book), Perl (with "perlinfo()", Guest Book), J2ee (with Info, Tomcat examples), Tools (with FileZilla FTP, Webalizer, Mail), and a copyright notice for Apache Friends. The main content area has sections for PDO Driver for SQLite 3.x, phalcon, and Phar. The "phalcon" section contains the following table:

phalcon	enabled
Author	Phalcon Team and contributors
Version	2.0.0
Powered by Zephir	Version 0.6.2a

`phpinfo()` will output a significant amount of information on screen about the current state of PHP. Scroll down to check if the phalcon extension has been loaded correctly.

The screenshot shows a Microsoft Edge browser window with the title bar "XAMPP 5.6.3". The address bar shows "localhost/xampp/index.php". Installation on WAMP

WampServer is a Windows web development environment. It allows you to create web applications with Apache2, PHP and a MySQL database. Below are detailed instructions on how to install Phalcon on WampServer for Windows. Using the latest WampServer version is highly recommended.

Download the right version of Phalcon WAMP has both 32 and 64 bit versions. From the download section, you can choose the Phalcon for Windows accordingly to your desired architecture.

After download the Phalcon library you will have a zip file like the one shown below:

Extract the library from the archive to get the Phalcon DLL:

Copy the file php_phalcon.dll to the PHP extensions. If WAMP is installed in the c:\wamp folder, the extension needs to be in C:\wamp\bin\php\php5.3.10\ext

Edit the php.ini file, it is located at C:\wamp\bin\php\php5.3.10\php.ini. It can be edited with Notepad or a similar program. We recommend Notepad++ to avoid issues with line endings. Append at the end of the file: extension=php_phalcon.dll and save it.

Also edit another php.ini file, which is located at C:\wamp\bin\apache\Apache2.2.21\bin\php.ini. Append at the end of the file: extension=php_phalcon.dll and save it.

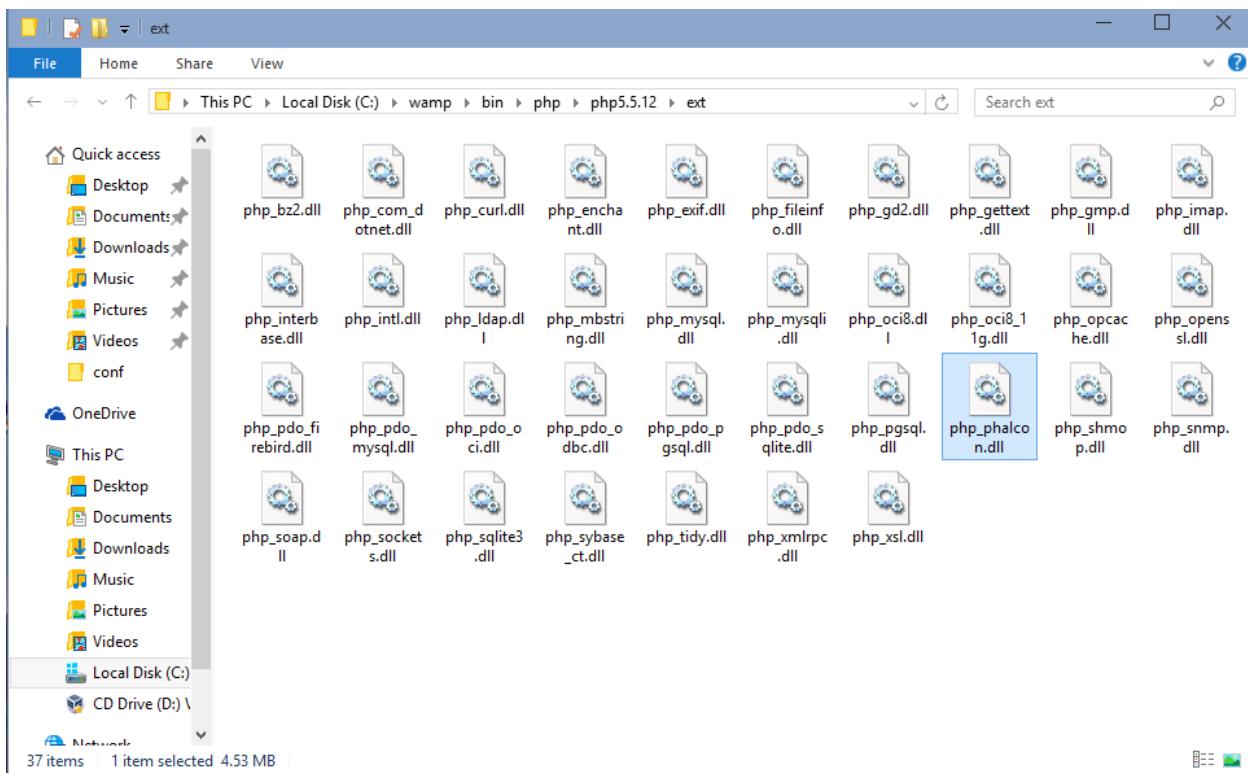

Restart the Apache Web Server. Do a single click on the WampServer icon at system tray. Choose “Restart All Services” from the pop-up menu. Check out that tray icon will become green again.

Open your browser to navigate to <http://localhost>. The WAMP welcome page will appear. Look at the section “extensions loaded” to check if phalcon was loaded.

Congrats!, You are now flying with Phalcon.

Version 2.5 [Version Française](#)

Server Configuration

Apache Version : 2.4.9 - [Documentation](#)

PHP Version : 5.5.12 - [Documentation](#)

Server Software: Apache/2.4.9 (Win64) PHP/5.5.12

Loaded Extensions :

apache2handler	bcmath	bz2	calendar	com_dotnet
Core	ctype	curl	date	dom
ereg	exif	fileinfo	filter	ftp
gd	gettext	gmp	hash	iconv
imap	json	libxml	mbstring	mcrypt
mhash	mysql	mysqli	mysqlind	odbc
openssl	pcre	PDO	pdo_mysql	pdo_sqlite
phalcon	Phar	Reflection	session	shmop
SimpleXML	soap	sockets	SPL	sqlite3
standard	tokenizer	wddx	xdebug	xml
xmlreader	xmlrpc	xmlwriter	xsl	zip
zlib				

MySQL Version : 5.6.17 - [Documentation](#)

- Detailed Installation on XAMPP for Windows

2.1.2 Linux/Solaris

On a Linux/Solaris system you can easily compile and install the extension from the source code:

Requirements

Prerequisite packages are:

- PHP >= 5.3 development resources
- GCC compiler (Linux/Solaris)
- Git (if not already installed in your system - unless you download the package from GitHub and upload it on your server via FTP/SFTP)

Specific packages for common platforms:

```
#Ubuntu
sudo apt-get install php5-dev libpcre3-dev gcc make php5-mysql

# Suse
sudo yast -i gcc make autoconf2.13 php5-devel php5-pear php5-mysql

# CentOS/RedHat/Fedora
sudo yum install php-devel pcre-devel gcc make
```

```
# Solaris
pkg install gcc-45 php-53 apache-php53
```

Compilation

Creating the extension:

```
git clone --depth=1 git://github.com/phalcon/cphalcon.git
cd cphalcon/build
sudo ./install
```

Add extension to your php configuration:

```
# Suse: Add this line in your php.ini
extension=phalcon.so

# CentOS/RedHat/Fedora: Add a file called phalcon.ini in /etc/php.d/ with this content:
extension=phalcon.so

# Ubuntu/Debian: Add a file called 30-phalcon.ini in /etc/php5/conf.d/ with this content:
extension=phalcon.so

# Debian with php5-fpm: Add a file called 30-phalcon.ini in /etc/php5/fpm/conf.d/30-phalcon.ini with
extension=phalcon.so
```

Restart the webserver.

If you are running Debian with php5-fpm, restart it:

```
sudo service php5-fpm restart
```

Phalcon automatically detects your architecture, however, you can force the compilation for a specific architecture:

```
cd cphalon/build
sudo ./install 32bits
sudo ./install 64bits
sudo ./install safe
```

If the automatic installer fails try building the extension manually:

```
cd cphalcon/build/64bits
export CFLAGS="-O2 --fvisibility=hidden"
./configure --enable-phalcon
make && sudo make install
```

2.1.3 Mac OS X

On a Mac OS X system you can compile and install the extension from the source code:

Requirements

Prerequisite packages are:

- PHP >= 5.4 development resources
- XCode

```
# brew
brew tap homebrew/homebrew-php
brew install php54-phalcon
brew install php55-phalcon
brew install php56-phalcon

# MacPorts
sudo port install php54-phalcon
sudo port install php55-phalcon
sudo port install php56-phalcon
```

Add extension to your php configuration:

2.1.4 FreeBSD

A port is available for FreeBSD. Just only need these simple line commands to install it:

```
pkg_add -r phalcon
```

or

```
export CFLAGS="-O2 --fvisibility=hidden"
cd /usr/ports/www/phalcon && make install clean
```

2.1.5 Installation Notes

Installation notes for Web Servers:

Apache Installation Notes

Apache is a popular and well known web server available on many platforms.

Configuring Apache for Phalcon

The following are potential configurations you can use to setup Apache with Phalcon. These notes are primarily focused on the configuration of the mod-rewrite module allowing to use friendly urls and the [router component](#). Commonly an application has the following structure:

```
test/
  app/
    controllers/
    models/
    views/
  public/
    css/
    img/
    js/
    index.php
```

Directory under the main Document Root This being the most common case, the application is installed in any directory under the document root. In this case, we use two .htaccess files, the first one to hide the application code forwarding all requests to the application's document root (public/).

```
# test/.htaccess

<IfModule mod_rewrite.c>
    RewriteEngine on
    RewriteRule ^$ public/ [L]
    RewriteRule (.*)
    RewriteRule (.*) public/$1 [L]
</IfModule>
```

Now a second .htaccess file is located in the public/ directory, this re-writes all the URIs to the public/index.php file:

```
# test/public/.htaccess

<IfModule mod_rewrite.c>
    RewriteEngine On
    RewriteCond %{REQUEST_FILENAME} !-d
    RewriteCond %{REQUEST_FILENAME} !-f
    RewriteRule ^(.*)$ index.php?_url=/{$1} [QSA,L]
</IfModule>
```

If you do not want to use .htaccess files you can move these configurations to the apache's main configuration file:

```
<IfModule mod_rewrite.c>

    <Directory "/var/www/test">
        RewriteEngine on
        RewriteRule ^$ public/ [L]
        RewriteRule (.*)
        RewriteRule (.*) public/$1 [L]
    </Directory>

    <Directory "/var/www/test/public">
        RewriteEngine On
        RewriteCond %{REQUEST_FILENAME} !-d
        RewriteCond %{REQUEST_FILENAME} !-f
        RewriteRule ^(.*)$ index.php?_url=/{$1} [QSA,L]
    </Directory>

</IfModule>
```

Virtual Hosts And this second configuration allows you to install a Phalcon application in a virtual host:

```
<VirtualHost *:80>

    ServerAdmin admin@example.host
    DocumentRoot "/var/vhosts/test/public"
    DirectoryIndex index.php
    ServerName example.host
    ServerAlias www.example.host

    <Directory "/var/vhosts/test/public">
        Options All
        AllowOverride All
        Allow from all
    </Directory>

</VirtualHost>
```

Nginx Installation Notes

Nginx is a free, open-source, high-performance HTTP server and reverse proxy, as well as an IMAP/POP3 proxy server. Unlike traditional servers, Nginx doesn't rely on threads to handle requests. Instead it uses a much more scalable event-driven (asynchronous) architecture. This architecture uses small, but more importantly, predictable amounts of memory under load.

The **PHP-FPM** (FastCGI Process Manager) is usually used to allow Nginx to process PHP files. Nowadays, **PHP-FPM** is bundled with any Unix PHP distribution. Phalcon + Nginx + **PHP-FPM** provides a powerful set of tools that offer maximum performance for your PHP applications.

Configuring Nginx for Phalcon

The following are potential configurations you can use to setup nginx with Phalcon:

Basic configuration Using `$_GET['_url']` as source of URIs:

```
server {

    listen     80;
    server_name localhost.dev;

    index index.php index.html index.htm;
    set $root_path '/var/www/phalcon/public';
    root $root_path;

    try_files $uri $uri/ @rewrite;

    location @rewrite {
        rewrite ^/(.*)$ /index.php?_url=/\$1;
    }

    location ~ \.php {
        fastcgi_pass unix:/run/php-fpm/php-fpm.sock;
        fastcgi_index /index.php;

        include /etc/nginx/fastcgi_params;

        fastcgi_split_path_info      ^(.+\.php) (/.+)$;
        fastcgi_param PATH_INFO      $fastcgi_path_info;
        fastcgi_param PATH_TRANSLATED $document_root$fastcgi_path_info;
        fastcgi_param SCRIPT_FILENAME $document_root$fastcgi_script_name;
    }

    location ~* ^/(css|img|js|flv|swf|download)/(.)$ {
        root $root_path;
    }

    location ~ /\.ht {
        deny all;
    }
}
```

Using `$_SERVER['REQUEST_URI']` as source of URIs:

```

server {

    listen 80;
    server_name localhost.dev;

    index index.php index.html index.htm;
    set $root_path '/var/www/phalcon/public';
    root $root_path;

    location / {
        try_files $uri $uri/ /index.php;
    }

    location ~ \.php$ {
        try_files $uri =404;
        fastcgi_split_path_info ^(.+\.php)(/.+)$;
        fastcgi_pass 127.0.0.1:9000;
        fastcgi_index index.php;
        fastcgi_param SCRIPT_FILENAME $document_root$fastcgi_script_name;
        include fastcgi_params;
    }

    location ~* ^/(css|img|js|flv|swf|download)/(.+)$ {
        root $root_path;
    }

    location ~ /\.ht {
        deny all;
    }
}

```

Dedicated Instance

```

server {
    listen 80;
    server_name localhost;

    charset utf-8;

    #access_log /var/log/nginx/host.access.log main;

    set $root_path '/srv/www/htdocs/phalcon-website/public';

    location / {
        root $root_path;
        index index.php index.html index.htm;

        # if file exists return it right away
        if (-f $request_filename) {
            break;
        }

        # otherwise rewrite it
        if (!-e $request_filename) {
            rewrite ^(.+)\$ /index.php?_url=/\$1 last;
            break;
        }
    }
}

```

```

location ~ \.php {
    # try_files      $uri =404;

    fastcgi_index /index.php;
    fastcgi_pass   127.0.0.1:9000;

    include fastcgi_params;
    fastcgi_split_path_info ^(.+\.php)(/.+)$;
    fastcgi_param PATH_INFO      $fastcgi_path_info;
    fastcgi_param PATH_TRANSLATED $document_root$fastcgi_path_info;
    fastcgi_param SCRIPT_FILENAME $document_root$fastcgi_script_name;
}

location ~* ^/(css|img|js|flv|swf|download) /(.+)$ {
    root $root_path;
}
}

```

Configuration by Host And this second configuration allow you to have different configurations by host:

```

server {
    listen      80;
    server_name localhost;
    set         $root_path '/var/www/$host/public';
    root       $root_path;

    access_log /var/log/nginx/$host-access.log;
    error_log  /var/log/nginx/$host-error.log error;

    index index.php index.html index.htm;

    try_files $uri $uri/ @rewrite;

    location @rewrite {
        rewrite ^/(.*)$ /index.php?_url=/\$1;
    }

    location ~ \.php {
        # try_files      $uri =404;

        fastcgi_index /index.php;
        fastcgi_pass   127.0.0.1:9000;

        include fastcgi_params;
        fastcgi_split_path_info ^(.+\.php)(/.+)$;
        fastcgi_param PATH_INFO      $fastcgi_path_info;
        fastcgi_param PATH_TRANSLATED $document_root$fastcgi_path_info;
        fastcgi_param SCRIPT_FILENAME $document_root$fastcgi_script_name;
    }

    location ~* ^/(css|img|js|flv|swf|download) /(.+)$ {
        root $root_path;
    }

    location ~ /\.ht {
        deny all;
    }
}

```

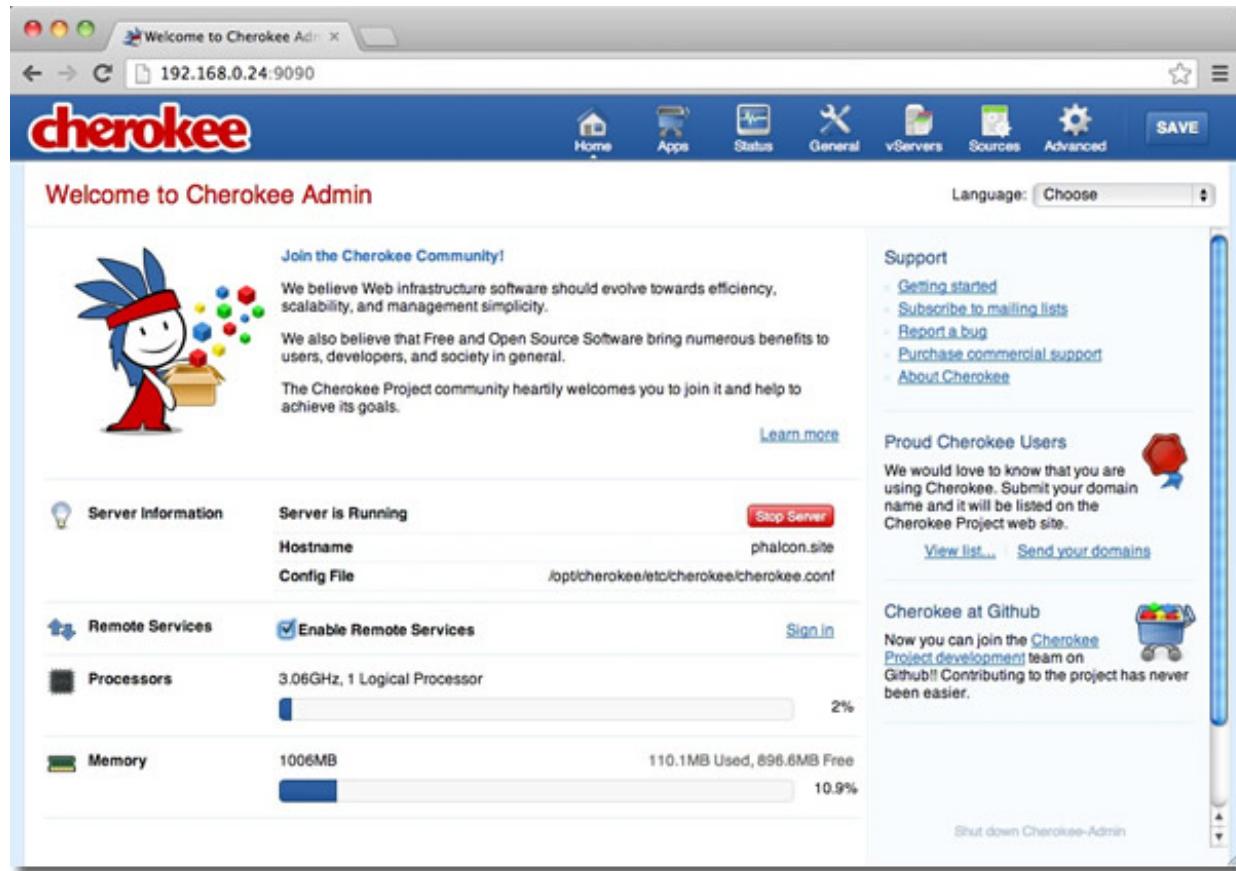

{}

Cherokee Installation Notes

Cherokee is a high-performance web server. It is very fast, flexible and easy to configure.

Configuring Cherokee for Phalcon

Cherokee provides a friendly graphical interface to configure almost every setting available in the web server. Start the cherokee administrator by executing with root /path-to-cherokee/sbin/cherokee-admin

Create a new virtual host by clicking on ‘vServers’, then add a new virtual server:

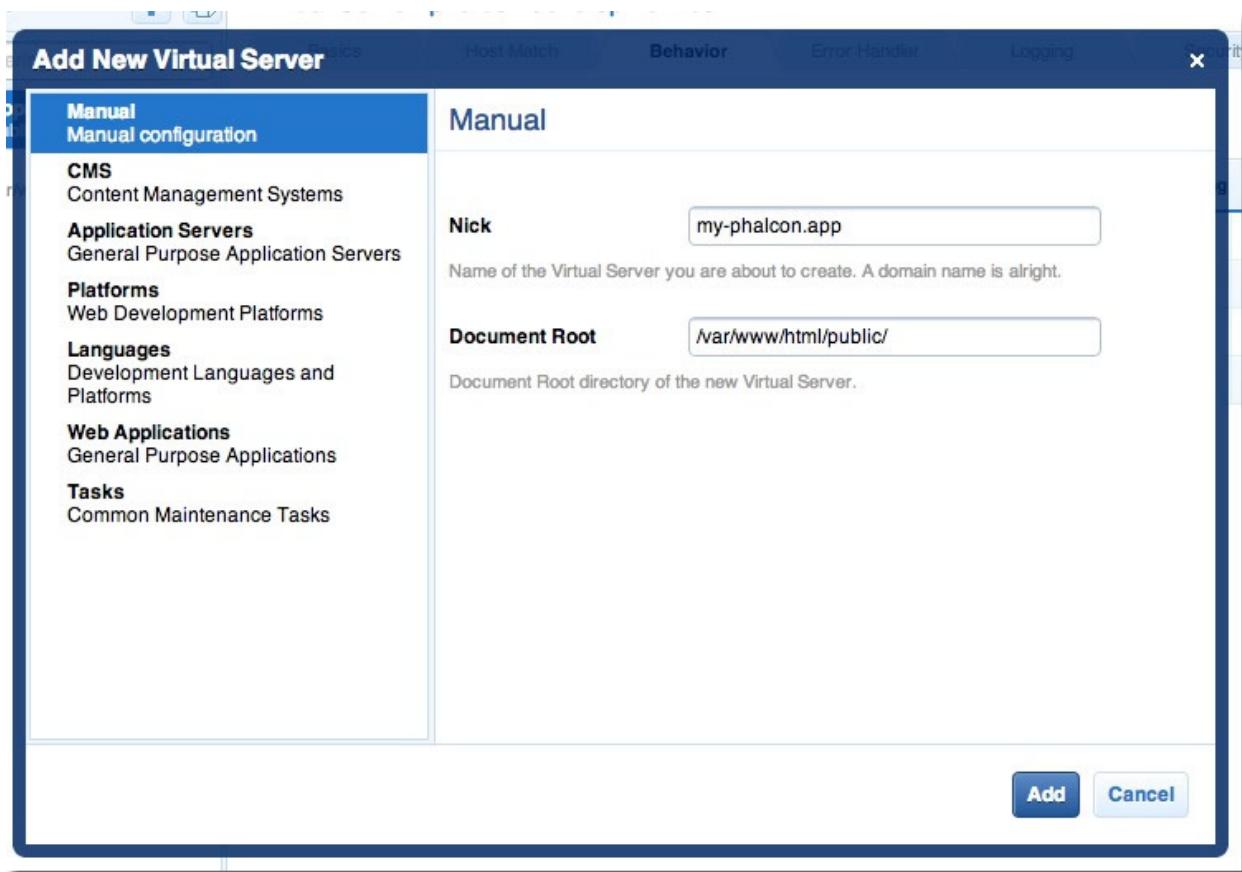

The recently added virtual server must appear at the left bar of the screen. In the ‘Behaviors’ tab you will see a set of default behaviors for this virtual server. Click the ‘Rule Management’ button. Remove those labeled as ‘Directory /cherokee_themes’ and ‘Directory /icons’:

Add the ‘PHP Language’ behavior using the wizard. This behavior allow you to run PHP applications:

Normally this behavior does not require additional settings. Add another behavior, this time in the ‘Manual Configuration’ section. In ‘Rule Type’ choose ‘File Exists’, then make sure the option ‘Match any file’ is enabled:

In the ‘Handler’ tab choose ‘List & Send’ as handler:

Edit the ‘Default’ behavior in order to enable the URL-rewrite engine. Change the handler to ‘Redirection’, then add the following regular expression to the engine `^(.*)$`:

Virtual Server: my-phalcon.app

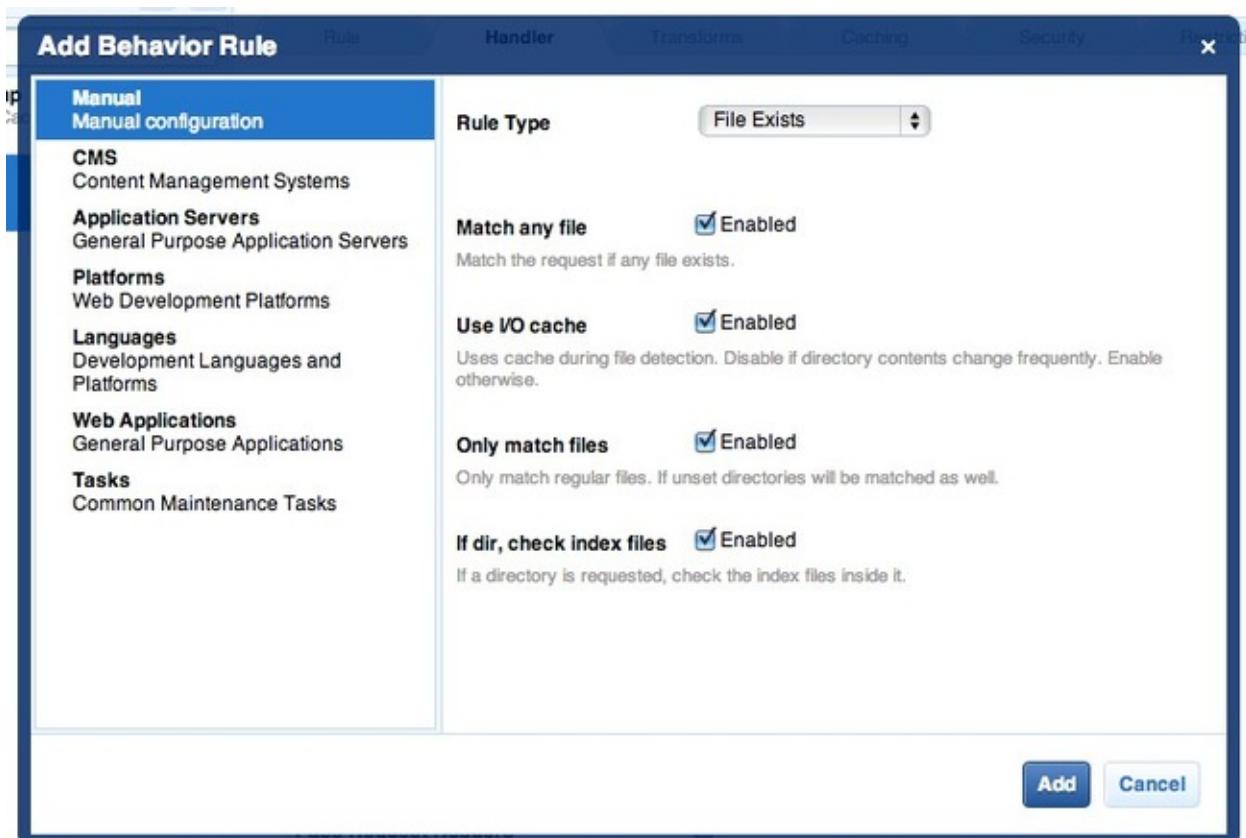

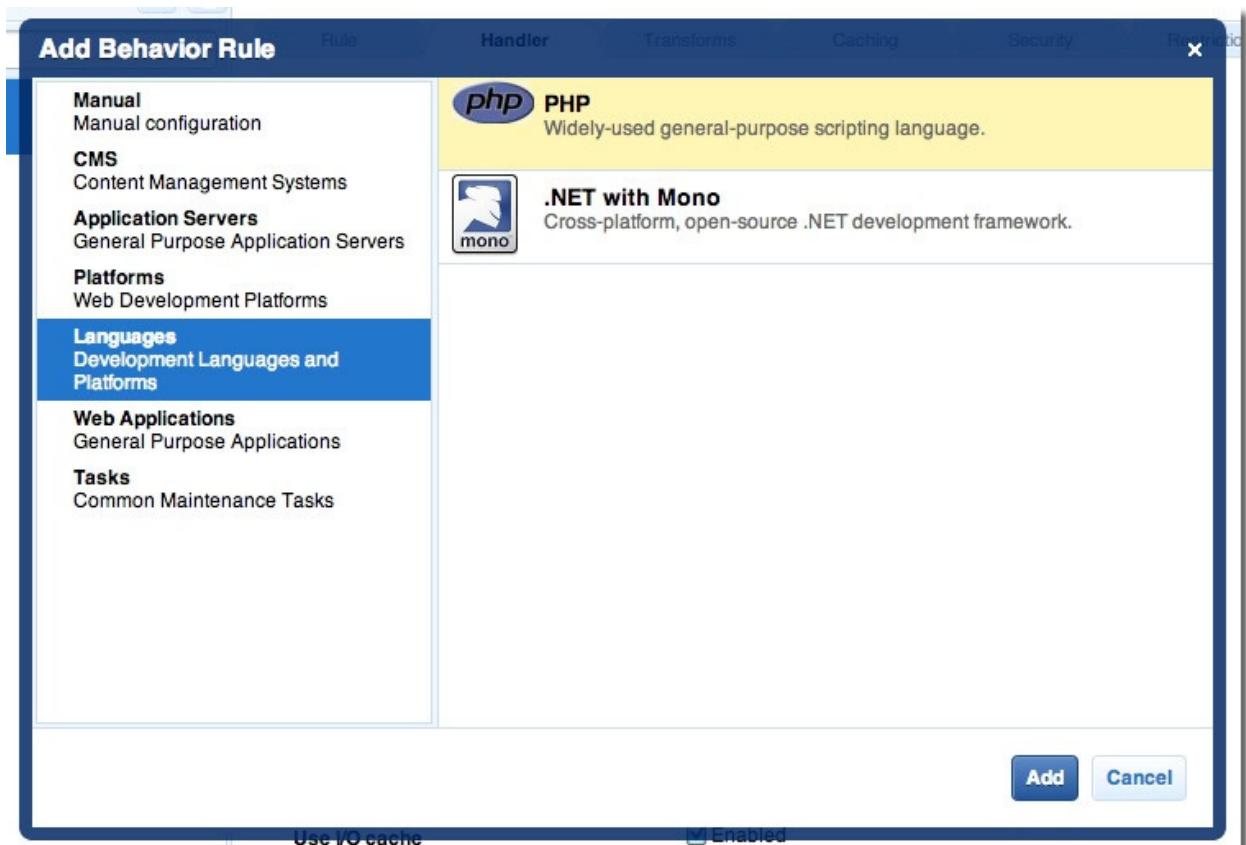

Help

Basics Host Match **Behavior** Error Handler Logging Security

Behavior Rules

Match	Handler	Auth	Root	Secure	Enc	Cache	Exp	Timeout	Shaping	Log	Final
Default	List & Send									✓	✓

Rule Management

The screenshot shows the Cherokee web interface for configuring a virtual server named 'my-phalcon.app'. The 'Handler' tab is selected. On the left, under 'Behavior', there is a list of rules:

- Extensions php**: FastCGI, gzip, Cache, Timeout (NON FINAL)
- File exists**: List & Send (FINAL)
- Default**: Redirection

In the main pane, the 'Handler' section is set to 'List & Send'. Below it, the 'Document Root' field is set to 'Optional'.

The screenshot shows the Cherokee web interface for configuring a virtual server named 'my-phalcon.app'. The 'Handler' tab is selected. On the left, under 'Behavior', there is a list of rules:

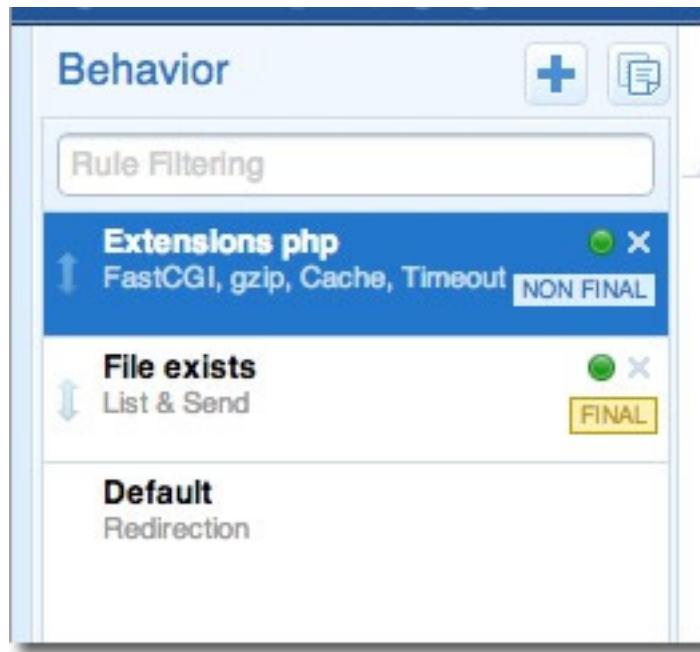

- Extensions php**: FastCGI, gzip, Cache, Timeout (NON FINAL)
- File exists**
- Default**: Redirection

In the main pane, the 'Handler' section is set to 'Redirection'. Below it, the 'Rule list' table shows one entry:

Type	Regular Expression	Substitution
Internal	<code>^(.*)\$</code>	<code>/index.php</code>

A blue button labeled 'Add New RegEx' is visible at the bottom of the rule list.

Finally, make sure the behaviors have the following order:

Execute the application in a browser:

Using PHP Built-in webserver

As of PHP 5.4.0, you can use PHP's built-in web server for development.

To start the server type:

```
php -S localhost:8000 -t /web_root
```

If you want to rewrite the URIs to the index.php file use the following router file (.htrouter.php):

```
<?php
if (!file_exists(__DIR__ . '/' . $_SERVER['REQUEST_URI'])) {
    $_GET['_url'] = $_SERVER['REQUEST_URI'];
}
return false;
```

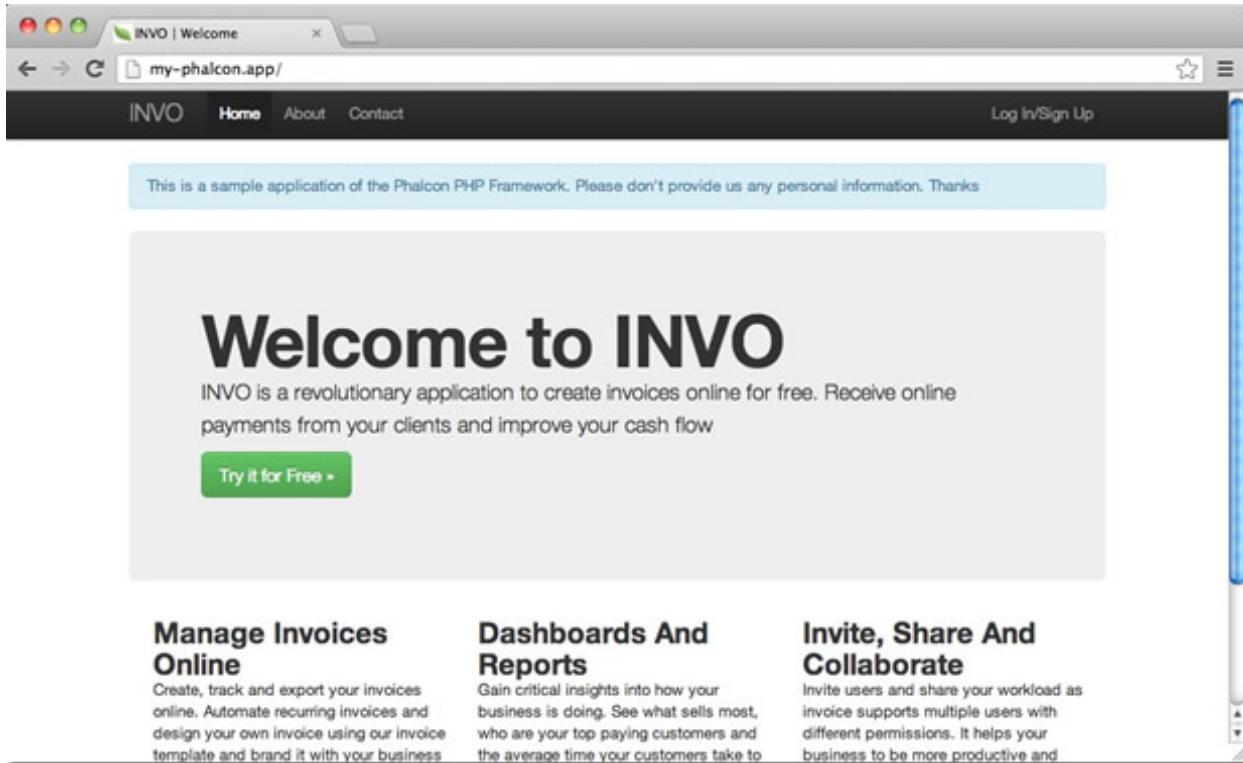

and then start the server from the base project directory with:

```
php -S localhost:8000 -t /public .htrouter.php
```

Then point your browser to <http://localhost:8000/> to check if everything is working.

2.2 Tutorial 1: Let's learn by example

Throughout this first tutorial, we'll walk you through the creation of an application with a simple registration form from the ground up. We will also explain the basic aspects of the framework's behavior. If you are interested in automatic code generation tools for Phalcon, you can check our [developer tools](#).

2.2.1 Checking your installation

We'll assume you have Phalcon installed already. Check your `phpinfo()` output for a section referencing "Phalcon" or execute the code snippet below:

```
<?php print_r(get_loaded_extensions()); ?>
```

The Phalcon extension should appear as part of the output:

```
Array
(
    [0] => Core
    [1] => libxml
    [2] => filter
    [3] => SPL
    [4] => standard
    [5] => phalcon
    [6] => pdo_mysql
)
```

2.2.2 Creating a project

The best way to use this guide is to follow each step in turn. You can get the complete code [here](#).

File structure

Phalcon does not impose a particular file structure for application development. Due to the fact that it is loosely coupled, you can implement Phalcon powered applications with a file structure you are most comfortable using.

For the purposes of this tutorial and as a starting point, we suggest this very simple structure:

```
tutorial/
  app/
    controllers/
    models/
    views/
  public/
    css/
    img/
    js/
```

Note that you don't need any "library" directory related to Phalcon. The framework is available in memory, ready for you to use.

Beautiful URLs

We'll use pretty (friendly) URLs for this tutorial. Friendly URLs are better for SEO as well as being easy for users to remember. Phalcon supports rewrite modules provided by the most popular web servers. Making your application's URLs friendly is not a requirement and you can just as easily develop without them.

In this example we'll use the rewrite module for Apache. Let's create a couple of rewrite rules in the /tutorial/.htaccess file:

```
#/tutorial/.htaccess
<IfModule mod_rewrite.c>
  RewriteEngine on
  RewriteRule ^$ public/ [L]
  RewriteRule (.*)
public/$1 [L]
</IfModule>
```

All requests to the project will be rewritten to the public/ directory making it the document root. This step ensures that the internal project folders remain hidden from public viewing and thus eliminates security threats of this kind.

The second set of rules will check if the requested file exists and, if it does, it doesn't have to be rewritten by the web server module:

```
#/tutorial/public/.htaccess
<IfModule mod_rewrite.c>
  RewriteEngine On
  RewriteCond %{REQUEST_FILENAME} !-d
  RewriteCond %{REQUEST_FILENAME} !-f
  RewriteRule ^(.*)$ index.php?url=/\$1 [QSA,L]
</IfModule>
```

Bootstrap

The first file you need to create is the bootstrap file. This file is very important; since it serves as the base of your application, giving you control of all aspects of it. In this file you can implement initialization of components as well as application behavior.

The tutorial/public/index.php file should look like:

```
<?php

use Phalcon\Loader;
use Phalcon\Mvc\View;
use Phalcon\Mvc\Application;
```

```
use Phalcon\DI\FactoryDefault;
use Phalcon\Mvc\Url as UrlProvider;
use Phalcon\Db\Adapter\Pdo\Mysql as DbAdapter;

try {

    // Register an autoloader
    $loader = new Loader();
    $loader->registerDirs(array(
        '../app/controllers/',
        '../app/models/'
    ))->register();

    // Create a DI
    $di = new FactoryDefault();

    // Setup the view component
    $di->set('view', function(){
        $view = new View();
        $view->setViewsDir('../app/views/');
        return $view;
    });

    // Setup a base URI so that all generated URIs include the "tutorial" folder
    $di->set('url', function(){
        $url = new UrlProvider();
        $url->setBaseUri('/tutorial/');
        return $url;
    });

    // Handle the request
    $application = new Application($di);

    echo $application->handle()->getContent();

} catch (\Exception $e) {
    echo "PhalconException: ", $e->getMessage();
}
```

Autoloaders

The first part that we find in the bootstrap is registering an autoloader. This will be used to load classes as controllers and models in the application. For example we may register one or more directories of controllers increasing the flexibility of the application. In our example we have used the component Phalcon\Loader.

With it, we can load classes using various strategies but for this example we have chosen to locate classes based on predefined directories:

```
<?php

use Phalcon\Loader;

// ...

$loader = new Loader();
$loader->registerDirs(
    array(
```

```

        '../app/controllers/',
        '../app/models/'
    )
) ->register();

```

Dependency Management

A very important concept that must be understood when working with Phalcon is its dependency injection container. It may sound complex but is actually very simple and practical.

A service container is a bag where we globally store the services that our application will use to function. Each time the framework requires a component, it will ask the container using an agreed upon name for the service. Since Phalcon is a highly decoupled framework, Phalcon\DI acts as glue facilitating the integration of the different components achieving their work together in a transparent manner.

```

<?php

use Phalcon\DI\FactoryDefault;

// ...

// Create a DI
$di = new FactoryDefault();

```

Phalcon\DI\FactoryDefault is a variant of Phalcon\DI. To make things easier, it has registered most of the components that come with Phalcon. Thus we should not register them one by one. Later there will be no problem in replacing a factory service.

In the next part, we register the “view” service indicating the directory where the framework will find the views files. As the views do not correspond to classes, they cannot be charged with an autoloader.

Services can be registered in several ways, but for our tutorial we’ll use an anonymous function:

```

<?php

use Phalcon\Mvc\View;

// ...

// Setup the view component
$di->set('view', function() {
    $view = new View();
    $view->setViewsDir('../app/views/');
    return $view;
});

```

Next we register a base URI so that all URIs generated by Phalcon include the “tutorial” folder we setup earlier. This will become important later on in this tutorial when we use the class Phalcon\Tag to generate a hyperlink.

```

<?php

use Phalcon\Mvc\Url as UrlProvider;

// ...

// Setup a base URI so that all generated URIs include the "tutorial" folder
$di->set('url', function(){
    $url = new UrlProvider();

```

```
$url->setBaseUri('/tutorial/');
return $url;
});
```

In the last part of this file, we find `Phalcon\Mvc\Application`. Its purpose is to initialize the request environment, route the incoming request, and then dispatch any discovered actions; it aggregates any responses and returns them when the process is complete.

```
<?php

use Phalcon\Mvc\Application;

// ...

$application = new Application($di);

echo $application->handle()->getContent();
```

As you can see, the bootstrap file is very short and we do not need to include any additional files. We have set ourselves a flexible MVC application in less than 30 lines of code.

Creating a Controller

By default Phalcon will look for a controller named “Index”. It is the starting point when no controller or action has been passed in the request. The index controller (`app/controllers/IndexController.php`) looks like:

```
<?php

use Phalcon\Mvc\Controller;

class IndexController extends Controller
{

    public function indexAction()
    {
        echo "<h1>Hello!</h1>";
    }
}
```

The controller classes must have the suffix “Controller” and controller actions must have the suffix “Action”. If you access the application from your browser, you should see something like this:

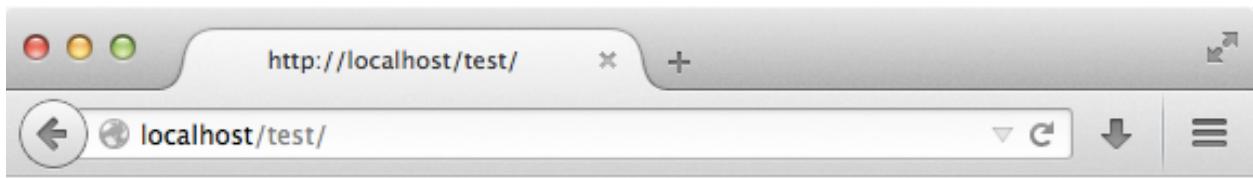

Congratulations, you’re flying with Phalcon!

Sending output to a view

Sending output to the screen from the controller is at times necessary but not desirable as most purists in the MVC community will attest. Everything must be passed to the view that is responsible for outputting data on screen. Phalcon will look for a view with the same name as the last executed action inside a directory named as the last executed controller. In our case (`app/views/index/index.phtml`):

```
<?php echo "<h1>Hello!</h1>";
```

Our controller (`app/controllers/IndexController.php`) now has an empty action definition:

Hello!

```
<?php

use Phalcon\Mvc\Controller;

class IndexController extends Controller
{

    public function indexAction()
    {

    }
}
```

The browser output should remain the same. The `Phalcon\Mvc\View` static component is automatically created when the action execution has ended. Learn more about [views](#) usage here .

Designing a sign up form

Now we will change the `index.phtml` view file, to add a link to a new controller named “`signup`”. The goal is to allow users to sign up within our application.

```
<?php

echo "<h1>Hello!</h1>";

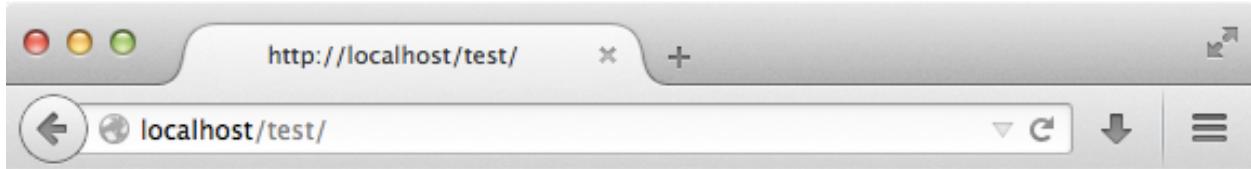

echo $this->tag->linkTo("signup", "Sign Up Here!");
```

The generated HTML code displays an anchor (“`a`”) HTML tag linking to a new controller:

```
<h1>Hello!</h1> <a href="/tutorial/signup">Sign Up Here!</a>
```

To generate the tag we use the class `Phalcon\Tag`. This is a utility class that allows us to build HTML tags with framework conventions in mind. As this class is also a service registered in the DI we use `$this->tag` to access it.

A more detailed article regarding HTML generation can be [found here](#)

Hello!

[Sign Up Here!](#)

Here is the Signup controller (`app/controllers/SignupController.php`):

```
<?php  
  
use Phalcon\Mvc\Controller;  
  
class SignupController extends Controller  
{  
  
    public function indexAction()  
    {  
  
    }  
}
```

The empty index action gives the clean pass to a view with the form definition (`app/views/signup/index.phtml`):

```
<h2>Sign up using this form</h2>  
  
<?php echo $this->tag->form("signup/register"); ?>  
  
<p>  
    <label for="name">Name</label>  
    <?php echo $this->tag->textField("name") ?>
```

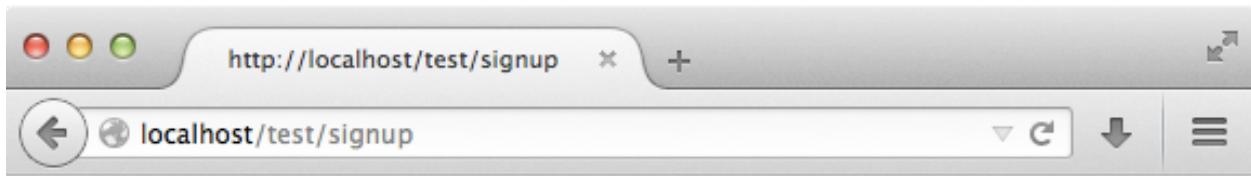

```
</p>

<p>
    <label for="email">E-Mail</label>
    <?php echo $this->tag->textField("email") ?>
</p>

<p>
    <?php echo $this->tag->submitButton("Register") ?>
</p>

</form>
```

Viewing the form in your browser will show something like this:

Sign using this form

Name

E-Mail

Phalcon\Tag also provides useful methods to build form elements.

The Phalcon\Tag::form method receives only one parameter for instance, a relative uri to a controller/action in the application.

By clicking the “Send” button, you will notice an exception thrown from the framework, indicating that we are missing the “register” action in the controller “signup”. Our public/index.php file throws this exception:

PhalconException: Action “register” was not found on controller “signup”

Implementing that method will remove the exception:

```
<?php

use Phalcon\Mvc\Controller;
```

```
class SignupController extends Controller
{
    public function indexAction()
    {
    }

    public function registerAction()
    {
    }
}
```

If you click the “Send” button again, you will see a blank page. The name and email input provided by the user should be stored in a database. According to MVC guidelines, database interactions must be done through models so as to ensure clean object-oriented code.

Creating a Model

Phalcon brings the first ORM for PHP entirely written in C-language. Instead of increasing the complexity of development, it simplifies it.

Before creating our first model, we need to create a database table outside of Phalcon to map it to. A simple table to store registered users can be defined like this:

```
CREATE TABLE `users` (
    `id` int(10) unsigned NOT NULL AUTO_INCREMENT,
    `name` varchar(70) NOT NULL,
    `email` varchar(70) NOT NULL,
    PRIMARY KEY (`id`)
);
```

A model should be located in the app/models directory (app/models/Users.php). The model maps to the “users” table:

```
<?php

use Phalcon\Mvc\Model;

class Users extends Model
{
    public $id;

    public $name;

    public $email;
}
```

Setting a Database Connection

In order to be able to use a database connection and subsequently access data through our models, we need to specify it in our bootstrap process. A database connection is just another service that our application has that can be used for several components:

```
<?php
```

```

use Phalcon\Loader;
use Phalcon\DI\FactoryDefault;
use Phalcon\Mvc\View;
use Phalcon\Mvc\Application;
use Phalcon\Mvc\Url as UrlProvider;
use Phalcon\Db\Adapter\Pdo\Mysql as DbAdapter;

try {

    // Register an autoloader
    $loader = new Loader();
    $loader->registerDirs(array(
        '../app/controllers/',
        '../app/models/'
    ))->register();

    // Create a DI
    $di = new FactoryDefault();

    // Setup the database service
    $di->set('db', function(){
        return new DbAdapter(array(
            "host"      => "localhost",
            "username"  => "root",
            "password"  => "secret",
            "dbname"    => "test_db"
        ));
    });

    // Setup the view component
    $di->set('view', function(){
        $view = new View();
        $view->setViewsDir('../app/views/');
        return $view;
    });

    // Setup a base URI so that all generated URIs include the "tutorial" folder
    $di->set('url', function(){
        $url = new UrlProvider();
        $url->setBaseUri('/tutorial/');
        return $url;
    });

    //Handle the request
    $application = new Application($di);

    echo $application->handle()->getContent();

} catch (\Exception $e) {
    echo "Exception: ", $e->getMessage();
}

```

With the correct database parameters, our models are ready to work and interact with the rest of the application.

Storing data using models

Receiving data from the form and storing them in the table is the next step.

```
<?php

use Phalcon\Mvc\Controller;

class SignupController extends Controller
{

    public function indexAction()
    {

    }

    public function registerAction()
    {

        $user = new Users();

        //Store and check for errors
        $success = $user->save($this->request->getPost(), array('name', 'email'));

        if ($success) {
            echo "Thanks for registering!";
        } else {
            echo "Sorry, the following problems were generated: ";
            foreach ($user->getMessages() as $message) {
                echo $message->getMessage(), "<br/>";
            }
        }

        $this->view->disable();
    }
}
```

We then instantiate the `Users` class, which corresponds to a `User` record. The class public properties map to the fields of the record in the `users` table. Setting the relevant values in the new record and calling `save()` will store the data in the database for that record. The `save()` method returns a boolean value which indicates whether the storing of the data was successful or not.

The ORM automatically escapes the input preventing SQL injections so we only need to pass the request to the `save` method.

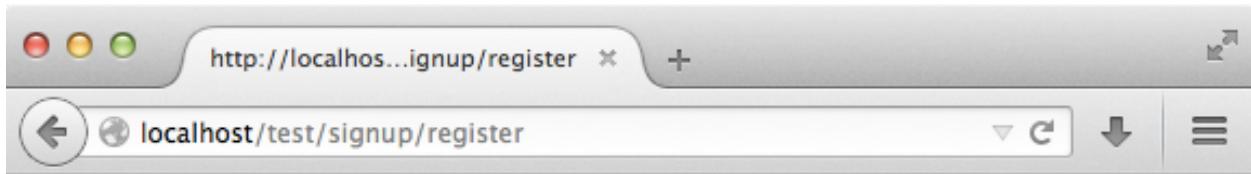

Additional validation happens automatically on fields that are defined as not null (required). If we don't enter any of the required fields in the sign up form our screen will look like this:

2.2.3 Conclusion

This is a very simple tutorial and as you can see, it's easy to start building an application using Phalcon. The fact that Phalcon is an extension on your web server has not interfered with the ease of development or features available. We invite you to continue reading the manual so that you can discover additional features offered by Phalcon!

2.3 Tutorial 2: Introducing INVO

In this second tutorial, we'll explain a more complete application in order to deepen the development with Phalcon. INVO is one of the applications we have created as samples. INVO is a small website that allows their users to generate invoices, and do other tasks such as manage their customers and products. You can clone its code from [Github](#).

Sorry, the following problems were generated: name is required
email is required

Also, INVO was made with [Bootstrap](#) as client-side framework. Although the application does not generate invoices, it still serves as an example to understand how the framework works.

2.3.1 Project Structure

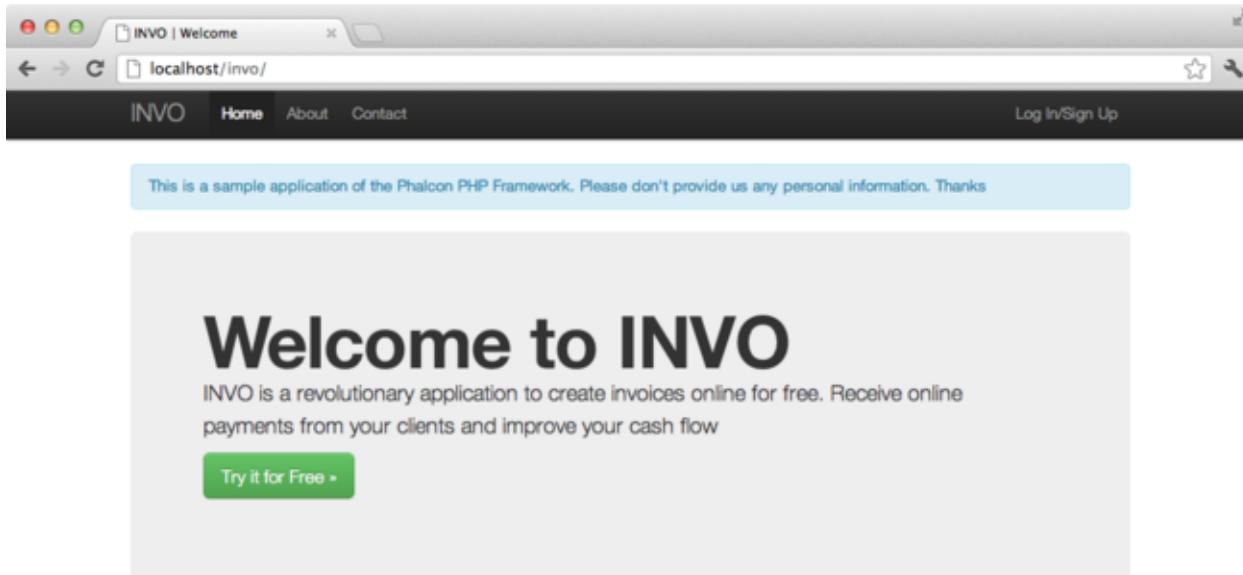

Once you clone the project in your document root you'll see the following structure:

```
invo/
  app/
    config/
    controllers/
    library/
    forms/
    models/
    plugins/
    views/
  public/
    bootstrap/
    css/
    js/
    schemas/
```

As you know, Phalcon does not impose a particular file structure for application development. This project provides a simple MVC structure and a public document root.

Once you open the application in your browser <http://localhost/invo> you'll see something like this:

The application is divided into two parts, a frontend, that is a public part where visitors can receive information about INVO and request contact information. The second part is the backend, an administrative area where a registered user can manage his/her products and customers.

Manage Invoices Online

Create, track and export your invoices online. Automate recurring invoices and design your own invoice using our invoice template and brand it with your business

Dashboards And Reports

Gain critical insights into how your business is doing. See what sells most, who are your top paying customers and the average time your customers take to

Invite, Share And Collaborate

Invite users and share your workload as INVO supports multiple users with different permissions. It helps your business to be more productive and

2.3.2 Routing

INVO uses the standard route that is built-in with the [Router](#) component. These routes match the following pattern: `/:controller/:action/:params`. This means that the first part of a URI is the controller, the second the action and the rest are the parameters.

The following route `/session/register` executes the controller `SessionController` and its action `registerAction`.

2.3.3 Configuration

INVO has a configuration file that sets general parameters in the application. This file is located at `app/config/config.ini` and it's loaded in the very first lines of the application bootstrap (`public/index.php`):

```
<?php

use Phalcon\Config\Adapter\Ini as ConfigIni;

// ...

/**
 * Read the configuration
 */
$config = new ConfigIni(APP_PATH . 'app/config/config.ini');
```

`Phalcon\Config` allows us to manipulate the file in an object-oriented way. In this example, we're using a ini file as configuration, however, there are more adapters supported for configuration files. The configuration file contains the following settings:

```
[database]
adapter  = Mysql
host     = localhost
username = root
password =
name     = invo

[application]
controllersDir = app/controllers/
modelsDir      = app/models/
viewsDir       = app/views/
pluginsDir     = app/plugins/
formsDir       = app/forms/
libraryDir     = app/library/
baseUri        = /invo/
```

Phalcon hasn't any pre-defined convention settings. Sections help us to organize the options as appropriate. In this file there are two sections to be used later "application" and "database".

2.3.4 Autoloaders

The second part that appears in the bootstrap file (public/index.php) is the autoloader:

```
<?php

/**
 * Auto-loader configuration
 */
require APP_PATH . 'app/config/loader.php';
```

The autoloader registers a set of directories in which the application will look for the classes that it eventually will need.

```
<?php

$loader = new \Phalcon\Loader();

/**
 * We're registering a set of directories taken from the configuration file
 */
$loader->registerDirs(
    array(
        APP_PATH . $config->application->controllersDir,
        APP_PATH . $config->application->pluginsDir,
        APP_PATH . $config->application->libraryDir,
        APP_PATH . $config->application->modelsDir,
        APP_PATH . $config->application->formsDir,
    )
)->register();
```

Note that the above code has registered the directories that were defined in the configuration file. The only directory that is not registered is the viewsDir, because it contains HTML + PHP files but no classes. Also, note that we have using a constant called APP_PATH, this constant is defined in the bootstrap (public/index.php) to allow us have a reference to the root of our project:

```
<?php
```

```
// ...  
  
define('APP_PATH', realpath('..') . '/');
```

2.3.5 Registering services

Another file that is required in the bootstrap is (app/config/services.php). This file allow us to organize the services that INVO does use.

```
<?php  
  
/**  
 * Load application services  
 */  
require APP_PATH . 'app/config/services.php';
```

Service registration is achieved as in the previous tutorial, making use of a closure to lazily loads the required components:

```
<?php  
  
use Phalcon\Mvc\Url as UrlProvider;  
  
// ...  
  
/**  
 * The URL component is used to generate all kind of urls in the application  
 */  
$di->set('url', function() use ($config){  
    $url = new UrlProvider();  
    $url->setBaseUri($config->application->baseUri);  
    return $url;  
});
```

We will discuss this file in depth later

2.3.6 Handling the Request

If we skip to the end of the file (public/index.php), the request is finally handled by Phalcon\Mvc\Application which initializes and executes all that is necessary to make the application run:

```
<?php  
  
use Phalcon\Mvc\Application;  
  
// ...  
  
$app = new Application($di);  
  
echo $app->handle()->getContent();
```

2.3.7 Dependency Injection

Look at the first line of the code block above, the Application class constructor is receiving the variable \$di as an argument. What is the purpose of that variable? Phalcon is a highly decoupled framework, so we need a component

that acts as glue to make everything work together. That component is Phalcon\DI. It is a service container that also performs dependency injection and service location, instantiating all components as they are needed by the application.

There are many ways of registering services in the container. In INVO, most services have been registered using anonymous functions/closures. Thanks to this, the objects are instantiated in a lazy way, reducing the resources needed by the application.

For instance, in the following excerpt the session service is registered. The anonymous function will only be called when the application requires access to the session data:

```
<?php

use Phalcon\Session\Adapter\Files as Session;

// ...

// Start the session the first time a component requests the session service
$di->set('session', function() {
    $session = new Session();
    $session->start();
    return $session;
});
```

Here, we have the freedom to change the adapter, perform additional initialization and much more. Note that the service was registered using the name “session”. This is a convention that will allow the framework to identify the active service in the services container.

A request can use many services and registering each service individually can be a cumbersome task. For that reason, the framework provides a variant of Phalcon\DI called Phalcon\DI\FactoryDefault whose task is to register all services providing a full-stack framework.

```
<?php

use Phalcon\DI\FactoryDefault;

// ...

// The FactoryDefault Dependency Injector automatically registers the
// right services providing a full-stack framework
$di = new FactoryDefault();
```

It registers the majority of services with components provided by the framework as standard. If we need to override the definition of some service we could just set it again as we did above with “session” or “url”. This is the reason for the existence of the variable \$di.

In next chapter, we will see how authentication and authorization is implemented in INVO.

2.4 Tutorial 3: Securing INVO

In this chapter, we continue explaining how INVO is structured, we’ll talk about the implementation of authentication, authorization using events and plugins and an access control list (ACL) managed by Phalcon.

2.4.1 Log into the Application

A “log in” facility will allow us to work on backend controllers. The separation between backend controllers and frontend ones is only logical. All controllers are located in the same directory (app/controllers/).

To enter the system, users must have a valid username and password. Users are stored in the table “users” in the database “invo”.

Before we can start a session, we need to configure the connection to the database in the application. A service called “db” is set up in the service container with the connection information. As with the autoloader, we are again taking parameters from the configuration file in order to configure a service:

```
<?php

use Phalcon\Db\Adapter\Pdo\Mysql as DbAdapter;

// ...

// Database connection is created based on parameters defined in the configuration file
$di->set('db', function() use ($config) {
    return new DbAdapter(array(
        "host"      => $config->database->host,
        "username"  => $config->database->username,
        "password"  => $config->database->password,
        "dbname"    => $config->database->name
    ));
});
```

Here, we return an instance of the MySQL connection adapter. If needed, you could do extra actions such as adding a logger, a profiler or change the adapter, setting it up as you want.

The following simple form (app/views/session/index.volt) requests the login information. We’ve removed some HTML code to make the example more concise:

```
{{ form('session/start') }}
<fieldset>
    <div>
        <label for="email">Username/Email</label>
        <div>
            {{ text_field('email') }}
        </div>
    </div>
    <div>
        <label for="password">Password</label>
        <div>
            {{ password_field('password') }}
        </div>
    </div>
    <div>
        {{ submit_button('Login') }}
    </div>
</fieldset>
</form>
```

Instead of using raw PHP as the previous tutorial, we started to use [Volt](#). This is a built-in template engine inspired in [Jinja](#) providing a simpler and friendly syntax to create templates. It will not take too long before you become familiar with Volt.

The SessionController::startAction function (app/controllers/SessionController.php) has the task of validating the data entered in the form including checking for a valid user in the database:

```
<?php

class SessionController extends ControllerBase
{
```

```
// ...

private function _registerSession($user)
{
    $this->session->set('auth', array(
        'id'      => $user->id,
        'name'    => $user->name
    ));
}

/**
 * This action authenticate and logs an user into the application
 */
public function startAction()
{
    if ($this->request->isPost()) {

        $email      = $this->request->getPost('email');
        $password   = $this->request->getPost('password');

        $user = Users::findFirst(array(
            '(email = :email: OR username = :email:) AND password = :password: AND active = "Y"',
            'bind' => array('email' => $email, 'password' => sha1($password))
        ));
        if ($user != false) {
            $this->_registerSession($user);
            $this->flash->success('Welcome ' . $user->name);
            return $this->forward('invoices/index');
        }

        $this->flash->error('Wrong email/password');
    }

    return $this->forward('session/index');
}
}
```

For the sake of simplicity, we have used “`sha1`” to store the password hashes in the database, however, this algorithm is not recommended in real applications, use “`bcrypt`” instead.

Note that multiple public attributes are accessed in the controller like: `$this->flash`, `$this->request` or `$this->session`. These are services defined in the services container from earlier (`app/config/services.php`). When they’re accessed the first time, they are injected as part of the controller.

These services are “shared”, which means that we are always accessing the same instance regardless of the place where we invoke them.

For instance, here we invoke the “`session`” service and then we store the user identity in the variable “`auth`”:

```
<?php

$this->session->set('auth', array(
    'id'      => $user->id,
    'name'    => $user->name
));
```

Another important aspect of this section is how the user is validated as a valid one, first we validate whether the request has been made using method POST:

```
<?php
if ($this->request->isPost()) {
```

Then, we receive the parameters from the form:

```
<?php
$email = $this->request->getPost('email');
$password = $this->request->getPost('password');
```

Now, we have to check if there is one user with the same username or email and password:

```
<?php
$user = Users::findFirst(array(
    "(email = :email: OR username = :email:) AND password = :password: AND active = 'Y'",
    'bind' => array('email' => $email, 'password' => sha1($password))
));
```

Note, the use of ‘bound parameters’, placeholders :email: and :password: are placed where values should be, then the values are ‘bound’ using the parameter ‘bind’. This safely replaces the values for those columns without having the risk of a SQL injection.

If the user is valid we register it in session and forwards him/her to the dashboard:

```
<?php
if ($user != false) {
    $this->registerSession($user);
    $this->flash->success('Welcome ' . $user->name);
    return $this->forward('invoices/index');
}
```

If the user does not exist we forward the user back again to action where the form is displayed:

```
<?php
return $this->forward('session/index');
```

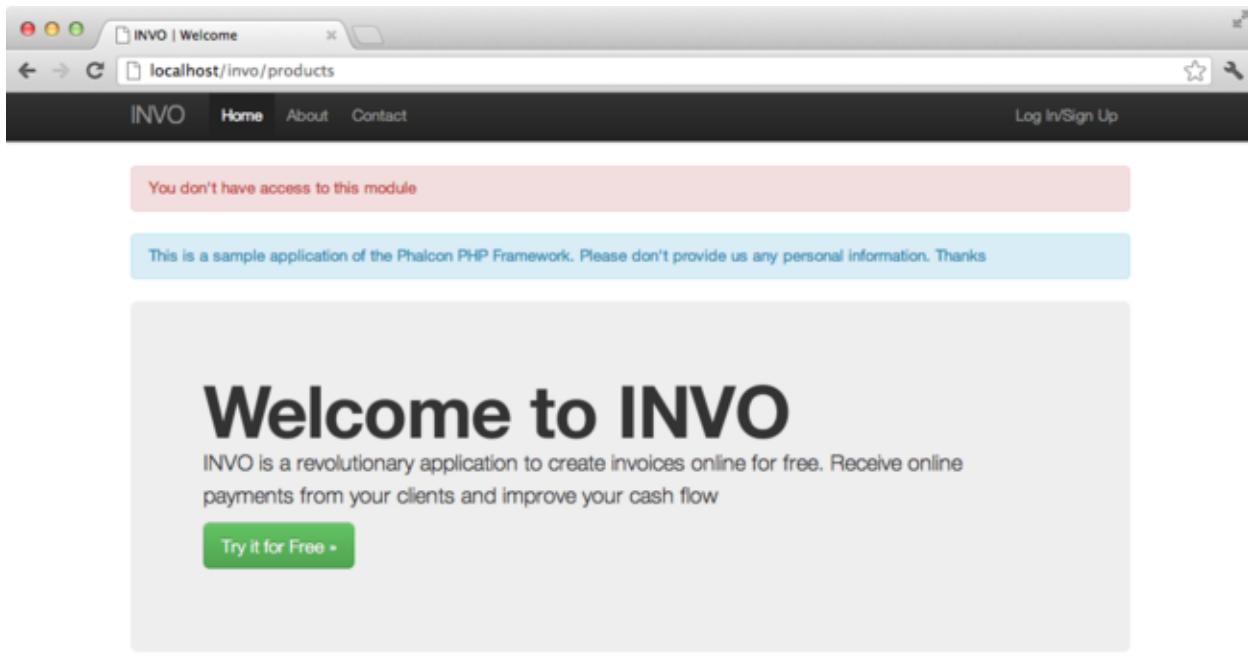

2.4.2 Securing the Backend

The backend is a private area where only registered users have access. Therefore, it is necessary to check that only registered users have access to these controllers. If you aren’t logged into the application and you try to access, for example, the products controller (which is private) you will see a screen like this:

Every time someone attempts to access any controller/action, the application verifies that the current role (in session) has access to it, otherwise it displays a message like the above and forwards the flow to the home page.

Now let’s find out how the application accomplishes this. The first thing to know is that there is a component called **Dispatcher**. It is informed about the route found by the **Routing** component. Then, it is responsible for loading the appropriate controller and execute the corresponding action method.

Normally, the framework creates the Dispatcher automatically. In our case, we want to perform a verification before executing the required action, checking if the user has access to it or not. To achieve this, we have replaced the component by creating a function in the bootstrap:

Manage Invoices Online

Create, track and export your invoices

Dashboards And Reports

Gain critical insights into how your

Invite, Share And Collaborate

Invite users and share your workload as

```
<?php

use Phalcon\Mvc\Dispatcher;

// ...

/**
 * MVC dispatcher
 */
$di->set('dispatcher', function() {

    // ...

    $dispatcher = new Dispatcher;

    return $dispatcher;
});
```

We now have total control over the Dispatcher used in the application. Many components in the framework trigger events that allow us to modify their internal flow of operation. As the Dependency Injector component acts as glue for components, a new component called [EventsManager](#) allows us to intercept the events produced by a component, routing the events to listeners.

Events Management

An [EventsManager](#) allows us to attach listeners to a particular type of event. The type that interests us now is “dispatch”. The following code filters all events produced by the Dispatcher:

```
<?php

use Phalcon\Mvc\Dispatcher;
use Phalcon\Events\Manager as EventsManager;

$di->set('dispatcher', function() {

    $eventsManager = new EventsManager;

    /**
     * Check if the user is allowed to access certain action using the SecurityPlugin
     */
    $eventsManager->attach('dispatch:beforeDispatch', new SecurityPlugin);

    /**
     * Handle exceptions and not-found exceptions using NotFoundPlugin
     */
    $eventsManager->attach('dispatch:beforeException', new NotFoundPlugin);

    $dispatcher = new Dispatcher;
    $dispatcher->setEventsManager($eventsManager);

    return $dispatcher;
});
```

When an event called “beforeDispatch” is triggered the following plugin will be notified:

```
<?php

/**
 * Check if the user is allowed to access certain action using the SecurityPlugin
 */
$eventsManager->attach('dispatch:beforeDispatch', new SecurityPlugin);
```

When a “beforeException” is triggered then other plugin is notified:

```
<?php

/**
 * Handle exceptions and not-found exceptions using NotFoundPlugin
 */
$eventsManager->attach('dispatch:beforeException', new NotFoundPlugin);
```

SecurityPlugin is a class located at (app/plugins/SecurityPlugin.php). This class implements the method “beforeDispatch”. This is the same name as one of the events produced in the Dispatcher:

```
<?php

use Phalcon\Acl;
use Phalcon\Events\Event;
use Phalcon\Mvc\User\Plugin;
use Phalcon\Mvc\Dispatcher;

class SecurityPlugin extends Plugin
{

    // ...

    public function beforeDispatch(Event $event, Dispatcher $dispatcher)
```

```
{
    // ...
}
```

The hook events always receive a first parameter that contains contextual information of the event produced (\$event) and a second one that is the object that produced the event itself (\$dispatcher). It is not mandatory that plugins extend the class Phalcon\Mvc\User\Plugin, but by doing this they gain easier access to the services available in the application.

Now, we're verifying the role in the current session, checking if the user has access using the ACL list. If the user does not have access we redirect to the home screen as explained before:

```
<?php

use Phalcon\Acl;
use Phalcon\Events\Event;
use Phalcon\Mvc\User\Plugin;
use Phalcon\Mvc\Dispatcher;

class Security extends Plugin
{

    // ...

    public function beforeExecuteRoute(Event $event, Dispatcher $dispatcher)
    {

        //Check whether the "auth" variable exists in session to define the active role
        $auth = $this->session->get('auth');
        if (!$auth) {
            $role = 'Guests';
        } else {
            $role = 'Users';
        }

        //Take the active controller/action from the dispatcher
        $controller = $dispatcher->getControllerName();
        $action = $dispatcher->getActionName();

        //Obtain the ACL list
        $acl = $this->getAcl();

        //Check if the Role have access to the controller (resource)
        $allowed = $acl->isAllowed($role, $controller, $action);
        if ($allowed != Acl::ALLOW) {

            //If he doesn't have access forward him to the index controller
            $this->flash->error("You don't have access to this module");
            $dispatcher->forward(
                array(
                    'controller' => 'index',
                    'action'      => 'index'
                )
            );

            //Returning "false" we tell to the dispatcher to stop the current operation
            return false;
        }
    }
}
```

```

    }
}

}
```

Providing an ACL list

In the above example we have obtained the ACL using the method `$this->_getAcl()`. This method is also implemented in the Plugin. Now we are going to explain step-by-step how we built the access control list (ACL):

```
<?php

use Phalcon\Acl;
use Phalcon\Acl\Role;
use Phalcon\Acl\Adapter\Memory as AclList;

// Create the ACL
$acl = new AclList();

// The default action is DENY access
$acl->setDefaultAction(Acl::DENY);

// Register two roles, Users is registered users
// and guests are users without a defined identity
$roles = array(
    'users' => new Role('Users'),
    'guests' => new Role('Guests')
);
foreach ($roles as $role) {
    $acl->addRole($role);
}
```

Now, we define the resources for each area respectively. Controller names are resources and their actions are accesses for the resources:

```
<?php

use Phalcon\Acl\Resource;

// ...

// Private area resources (backend)
$privateResources = array(
    'companies' => array('index', 'search', 'new', 'edit', 'save', 'create', 'delete'),
    'products' => array('index', 'search', 'new', 'edit', 'save', 'create', 'delete'),
    'producttypes' => array('index', 'search', 'new', 'edit', 'save', 'create', 'delete'),
    'invoices' => array('index', 'profile')
);
foreach ($privateResources as $resource => $actions) {
    $acl->addResource(new Resource($resource), $actions);
}

// Public area resources (frontend)
$publicResources = array(
    'index' => array('index'),
    'about' => array('index'),
    'register' => array('index'),
    'errors' => array('show404', 'show500'),
}
```

```

'session'      => array('index', 'register', 'start', 'end'),
'contact'     => array('index', 'send')
);
foreach ($publicResources as $resource => $actions) {
    $acl->addResource(new Resource($resource), $actions);
}

```

The ACL now have knowledge of the existing controllers and their related actions. Role “Users” has access to all the resources of both frontend and backend. The role “Guests” only has access to the public area:

```

<?php

// Grant access to public areas to both users and guests
foreach ($roles as $role) {
    foreach ($publicResources as $resource => $actions) {
        $acl->allow($role->getName(), $resource, '*');
    }
}

// Grant access to private area only to role Users
foreach ($privateResources as $resource => $actions) {
    foreach ($actions as $action) {
        $acl->allow('Users', $resource, $action);
    }
}

```

Hooray!, the ACL is now complete. In next chapter, we will see how a CRUD is implemented in Phalcon and how you can customize it.

2.5 Tutorial 4: Using CRUDs

Backends usually provides forms to allow users to manipulate data. Continuing the explanation of INVO, we now address the creation of CRUDs, a very common task that Phalcon will facilitate you using forms, validations, paginators and more.

2.5.1 Working with the CRUD

Most options that manipulate data in INVO (companies, products and types of products), were developed using a basic and common **CRUD** (Create, Read, Update and Delete). Each CRUD contains the following files:

```

invo/
    app/
        controllers/
            ProductsController.php
        models/
            Products.php
        forms/
            ProductsForm.php
    views/
        products/
            edit.volt
            index.volt
            new.volt
            search.volt

```

Each controller has the following actions:

```
<?php

class ProductsController extends ControllerBase
{

    /**
     * The start action, it shows the "search" view
     */
    public function indexAction()
    {
        //...
    }

    /**
     * Execute the "search" based on the criteria sent from the "index"
     * Returning a paginator for the results
     */
    public function searchAction()
    {
        //...
    }

    /**
     * Shows the view to create a "new" product
     */
    public function newAction()
    {
        //...
    }

    /**
     * Shows the view to "edit" an existing product
     */
    public function editAction()
    {
        //...
    }

    /**
     * Creates a product based on the data entered in the "new" action
     */
    public function createAction()
    {
        //...
    }

    /**
     * Updates a product based on the data entered in the "edit" action
     */
    public function saveAction()
    {
        //...
    }

    /**
     * Deletes an existing product
     */
}
```

```

public function deleteAction($id)
{
    //...
}

}

```

The Search Form

Every CRUD starts with a search form. This form shows each field that has the table (products), allowing the user to create a search criteria from any field. Table “products” has a relationship to the table “products_types”. In this case, we previously queried the records in this table in order to facilitate the search by that field:

```

<?php

/**
 * The start action, it shows the "search" view
 */
public function indexAction()
{
    $this->persistent->searchParams = null;
    $this->view->form = new ProductsForm;
}

```

An instance of the form ProductsForm (app/forms/ProductsForm.php) is passed to the view. This form defines the fields that are visible to the user:

```

<?php

use Phalcon\Forms\Form;
use Phalcon\Forms\Element\Text;
use Phalcon\Forms\Element\Hidden;
use Phalcon\Forms\Element\Select;
use Phalcon\Validation\Validator\Email;
use Phalcon\Validation\Validator\PresenceOf;
use Phalcon\Validation\Validator\Numericality;

class ProductsForm extends Form
{

    /**
     * Initialize the products form
     */
    public function initialize($entity = null, $options = array())
    {

        if (!isset($options['edit'])) {
            $element = new Text("id");
            $this->add($element->setLabel("Id"));
        } else {
            $this->add(new Hidden("id"));
        }

        $name = new Text("name");
        $name->setLabel("Name");
        $name->setFilters(array('striptags', 'string'));
        $name->addValidators(array(

```

```

        new PresenceOf(array(
            'message' => 'Name is required'
        )));
    );
    $this->add($name);

    $type = new Select('profilesId', ProductTypes::find(), array(
        'using'      => array('id', 'name'),
        'useEmpty'   => true,
        'emptyText'  => '...',
        'emptyValue' => ''
    ));
    $this->add($type);

    $price = new Text("price");
    $price->setLabel("Price");
    $price->setFilters(array('float'));
    $price->addValidators(array(
        new PresenceOf(array(
            'message' => 'Price is required'
        )),
        new Numericality(array(
            'message' => 'Price is required'
        ))
    ));
    $this->add($price);
}
}

```

The form is declared using an object-oriented scheme based on the elements provided by the `forms` component. Every element follows almost the same structure:

```

<?php

// Create the element
$name = new Text("name");

// Set its label
$name->setLabel("Name");

// Before validating the element apply these filters
$name->setFilters(array('striptags', 'string'));

// Apply this validators
$name->addValidators(array(
    new PresenceOf(array(
        'message' => 'Name is required'
    )))
);

// Add the element to the form
$this->add($name);

```

Other elements are also used in this form:

```

<?php

// Add a hidden input to the form
$this->add(new Hidden("id"));

```

```
// ...

// Add a HTML Select (list) to the form
// and fill it with data from "product_types"
$type = new Select('profilesId', ProductTypes::find(), array(
    'using'      => array('id', 'name'),
    'useEmpty'   => true,
    'emptyText'  => '...',
    'emptyValue' => ''
));

```

Note that `ProductTypes::find()` contains the data necessary to fill the `SELECT` tag using `Phalcon\Tag::select`. Once the form is passed to the view, it can be rendered and presented to the user:

```
{{ form("products/search") }}

<h2>Search products</h2>

<fieldset>

    {%
        for element in form %
            <div class="control-group">
                {{ element.label(['class': 'control-label']) }} 
                <div class="controls">{{ element }}</div>
            </div>
    % endfor %

    <div class="control-group">
        {{ submit_button("Search", "class": "btn btn-primary") }}
    </div>
</fieldset>
```

This produces the following HTML:

```
<form action="/invo/products/search" method="post">

<h2>Search products</h2>

<fieldset>

    <div class="control-group">
        <label for="id" class="control-label">Id</label>
        <div class="controls"><input type="text" id="id" name="id" /></div>
    </div>

    <div class="control-group">
        <label for="name" class="control-label">Name</label>
        <div class="controls">
            <input type="text" id="name" name="name" />
        </div>
    </div>

    <div class="control-group">
        <label for="profilesId" class="control-label">profilesId</label>
        <div class="controls">
            <select id="profilesId" name="profilesId">
                <option value="">...</option>

```

```

        <option value="1">Vegetables</option>
        <option value="2">Fruits</option>
    </select>
</div>
</div>

<div class="control-group">
    <label for="price" class="control-label">Price</label>
    <div class="controls"><input type="text" id="price" name="price" /></div>
</div>

<div class="control-group">
    <input type="submit" value="Search" class="btn btn-primary" />
</div>

</fieldset>
```

When the form is submitted, the action “search” is executed in the controller performing the search based on the data entered by the user.

Performing a Search

The action “search” has a dual behavior. When accessed via POST, it performs a search based on the data sent from the form. But when accessed via GET it moves the current page in the paginator. To differentiate one from another HTTP method, we check it using the [Request component](#):

```

<?php

/**
 * Execute the "search" based on the criteria sent from the "index"
 * Returning a paginator for the results
 */
public function searchAction()
{
    if ($this->request->isPost()) {
        //create the query conditions
    } else {
        //paginate using the existing conditions
    }

    //...
}
```

With the help of [Phalcon\Mvc\Model\Criteria](#), we can create the search conditions intelligently based on the data types and values sent from the form:

```

<?php
$query = Criteria::fromInput($this->di, "Products", $this->request->getPost());
```

This method verifies which values are different from “” (empty string) and null and takes them into account to create the search criteria:

- If the field data type is text or similar (char, varchar, text, etc.) It uses an SQL “like” operator to filter the results.
- If the data type is not text or similar, it’ll use the operator “=”.

Additionally, “Criteria” ignores all the `$_POST` variables that do not match any field in the table. Values are automatically escaped using “bound parameters”.

Now, we store the produced parameters in the controller’s session bag:

```
<?php
$this->persistent->searchParams = $query->getParams();
```

A session bag, is a special attribute in a controller that persists between requests using the session service. When accessed, this attribute injects a `Phalcon\Session\Bag` instance that is independent in each controller.

Then, based on the built params we perform the query:

```
<?php
$products = Products::find($parameters);
if (count($products) == 0) {
    $this->flash->notice("The search did not found any products");
    return $this->forward("products/index");
}
```

If the search doesn’t return any product, we forward the user to the index action again. Let’s pretend the search returned results, then we create a paginator to navigate easily through them:

```
<?php
use Phalcon\Paginator\Adapter\Model as Paginator;

// ...

$paginator = new Paginator(array(
    "data" => $products, // Data to paginate
    "limit" => 5, // Rows per page
    "page" => $numberPage // Active page
));

// Get active page in the paginator
$page = $paginator->getPaginate();
```

Finally we pass the returned page to view:

```
<?php
$this->view->page = $page;
```

In the view (app/views/products/search.phtml), we traverse the results corresponding to the current page, showing every row in the current page to the user:

```
{% for product in page.items %}
{% if loop.first %}
<table>
<thead>
<tr>
<th>Id</th>
<th>Product Type</th>
<th>Name</th>
<th>Price</th>
<th>Active</th>
</tr>
```

```
</thead>
<tbody>
{%
    endif %
}
<tr>
    <td>{{ product.id }}</td>
    <td>{{ product.getProductTypes().name }}</td>
    <td>{{ product.name }}</td>
    <td>{{ "%.2f" | format(product.price) }}</td>
    <td>{{ product.getActiveDetail() }}</td>
    <td width="7%">{{ link_to("products/edit/" ~ product.id, 'Edit') }}</td>
    <td width="7%">{{ link_to("products/delete/" ~ product.id, 'Delete') }}</td>
</tr>
{%
    if loop.last %
}
</tbody>
<tbody>
    <tr>
        <td colspan="7">
            <div>
                {{ link_to("products/search", 'First') }}
                {{ link_to("products/search?page=" ~ page.before, 'Previous') }}
                {{ link_to("products/search?page=" ~ page.next, 'Next') }}
                {{ link_to("products/search?page=" ~ page.last, 'Last') }}
                <span class="help-inline">{{ page.current }} of {{ page.total_pages }}</span>
            </div>
        </td>
    </tr>
</tbody>
</table>
{%
    endif %
}
{%
    else %
}
    No products are recorded
{%
    endfor %
}
```

There are many things in the above example that worth detailing. First of all, active items in the current page are traversed using a Volt's 'for'. Volt provides a simpler syntax for a PHP 'foreach'.

```
{%
    for product in page.items %
}
```

Which in PHP is the same as:

```
<?php foreach ($page->items as $product) { ?>
```

The whole 'for' block provides the following:

```
{% for product in page.items %}
    {% if loop.first %} Executed before the first product in the loop
    {% endif %} Executed for every product of page.items
    {% if loop.last %} Executed after the last product is loop
    {% endif %}
    {% else %} Executed if page.items does not have any products
    {% endfor %}
```

Now you can go back to the view and find out what every block is doing. Every field in "product" is printed accordingly:

```
<tr>
    <td>{{ product.id }}</td>
    <td>{{ product.productTypes.name }}</td>
    <td>{{ product.name }}</td>
    <td>{{ "%.2f" | format(product.price) }}</td>
    <td>{{ product.getActiveDetail() }}</td>
    <td width="7%">{{ link_to("products/edit/" ~ product.id, 'Edit') }}</td>
    <td width="7%">{{ link_to("products/delete/" ~ product.id, 'Delete') }}</td>
</tr>
```

As we seen before using `product.id` is the same as in PHP as doing: `$product->id`, we made the same with `product.name` and so on. Other fields are rendered differently, for instance, let's focus in `product.productTypes.name`. To understand this part, we have to check the model `Products` (`app/models/Products.php`):

```
<?php

use Phalcon\Mvc\Model;

/**
 * Products
 */
class Products extends Model
{
    // ...

    /**
     * Products initializer
     */
    public function initialize()
    {
        $this->belongsTo('product_types_id', 'ProductTypes', 'id', array(
            'reusable' => true
        ));
    }

    // ...
}
```

A model, can have a method called “`initialize`”, this method is called once per request and it serves the ORM to initialize a model. In this case, “`Products`” is initialized by defining that this model has a one-to-many relationship to another model called “`ProductTypes`”.

```
<?php

$this->belongsTo('product_types_id', 'ProductTypes', 'id', array(
    'reusable' => true
));
```

Which means, the local attribute “`product_types_id`” in “`Products`” has an one-to-many relation to the model “`ProductTypes`” in its attribute “`id`”. By defining this relation we can access the name of the product type by using:

```
<td>{{ product.productTypes.name }}</td>
```

The field “`price`” is printed by its formatted using a Volt filter:

```
<td>{{ "%.2f" | format(product.price) }}</td>
```

What in PHP would be:

```
<?php echo sprintf("%.2f", $product->price) ?>
```

Printing whether the product is active or not uses a helper implemented in the model:

```
<td>{{ product.getActiveDetail() }}</td>
```

This method is defined in the model:

Creating and Updating Records

Now let's see how the CRUD creates and updates records. From the "new" and "edit" views the data entered by the user are sent to the actions "create" and "save" that perform actions of "creating" and "updating" products respectively.

In the creation case, we recover the data submitted and assign them to a new "products" instance:

```
<?php

/**
 * Creates a new product
 */
public function createAction()
{
    if (!$this->request->isPost()) {
        return $this->forward("products/index");
    }

    $form     = new ProductsForm;
    $product  = new Products();

    // ...
}
```

Remember the filters we defined in the Products form? Data is filtered before being assigned to the object \$product. This filtering is optional, also the ORM escapes the input data and performs additional casting according to the column types:

```
<?php

// ...

$name = new Text("name");
$name->setLabel("Name");

// Filters for name
$name->setFilters(array('striptags', 'string'));

// Validators for name
$name->addValidators(array(
    new PresenceOf(array(
        'message' => 'Name is required'
    ))
));

$this->add($name);
```

When saving we'll know whether the data conforms to the business rules and validations implemented in the form ProductsForm (app/forms/ProductsForm.php):

```
<?php

// ...

$form = new ProductsForm;
$product = new Products();

// Validate the input
$data = $this->request->getPost();
if (!$form->isValid($data, $product)) {
    foreach ($form->getMessages() as $message) {
        $this->flash->error($message);
    }
    return $this->forward('products/new');
}
```

Finally, if the form does not return any validation message we can save the product instance:

```
<?php

// ...

if ($product->save() == false) {
    foreach ($product->getMessages() as $message) {
        $this->flash->error($message);
    }
    return $this->forward('products/new');
}

$form->clear();

$this->flash->success("Product was created successfully");
return $this->forward("products/index");
```

Now, in the case of product updating, first we must present to the user the data that is currently in the edited record:

```
<?php

/**
 * Edits a product based on its id
 */
public function editAction($id)
{

    if (!$this->request->isPost()) {

        $product = Products::findFirstBy($id);
        if (!$product) {
            $this->flash->error("Product was not found");
            return $this->forward("products/index");
        }

        $this->view->form = new ProductsForm($product, array('edit' => true));
    }
}
```

The data found is bound to the form passing the model as first parameter. Thanks to this, the user can change any value and then sent it back to the database through to the “save” action:

```
<?php

/**
 * Saves current product in screen
 *
 * @param string $id
 */
public function saveAction()
{
    if (!$this->request->isPost()) {
        return $this->forward("products/index");
    }

    $id = $this->request->getPost("id", "int");
    $product = Products::findFirstById($id);
    if (!$product) {
        $this->flash->error("Product does not exist");
        return $this->forward("products/index");
    }

    $form = new ProductsForm;

    $data = $this->request->getPost();
    if (!$form->isValid($data, $product)) {
        foreach ($form->getMessages() as $message) {
            $this->flash->error($message);
        }
        return $this->forward('products/new');
    }

    if ($product->save() == false) {
        foreach ($product->getMessages() as $message) {
            $this->flash->error($message);
        }
        return $this->forward('products/new');
    }

    $form->clear();

    $this->flash->success("Product was updated successfully");
    return $this->forward("products/index");
}
```

We have seen how Phalcon lets you create forms and bind data from a database in a structured way. In next chapter, we will see how to add custom HTML elements like a menu.

2.6 Tutorial 5: Customizing INVO

To finish the detailed explanation of INVO we are going to explain how to customize INVO adding UI elements and changing the title according to the controller executed.

2.6.1 User Components

All the UI elements and visual style of the application has been achieved mostly through [Bootstrap](#). Some elements, such as the navigation bar changes according to the state of the application. For example, in the upper right corner, the

link “Log in / Sign Up” changes to “Log out” if an user is logged into the application.

This part of the application is implemented in the component “Elements” (app/library/Elements.php).

```
<?php

use Phalcon\Mvc\User\Component;

class Elements extends Component
{

    public function getMenu()
    {
        //...
    }

    public function getTabs()
    {
        //...
    }

}
```

This class extends the Phalcon\Mvc\User\Component. It is not imposed to extend a component with this class, but it helps to get access more quickly to the application services. Now, we are going to register our first user component in the services container:

```
<?php

//Register an user component
$di->set('elements', function(){
    return new Elements();
});
```

As controllers, plugins or components within a view, this component also has access to the services registered in the container and by just accessing an attribute with the same name as a previously registered service:

```
<div class="navbar navbar-fixed-top">
    <div class="navbar-inner">
        <div class="container">
            <a class="btn btn-navbar" data-toggle="collapse" data-target=".nav-collapse">
                <span class="icon-bar"></span>
                <span class="icon-bar"></span>
                <span class="icon-bar"></span>
            </a>
            <a class="brand" href="#">INVO</a>
            {{ elements.getMenu() }}
        </div>
    </div>
</div>

<div class="container">
    {{ content() }}
    <hr>
    <footer>
        <p>&copy; Company 2014</p>
    </footer>
</div>
```

The important part is:

```
{ { elements.getMenu() } }
```

2.6.2 Changing the Title Dynamically

When you browse between one option and another will see that the title changes dynamically indicating where we are currently working. This is achieved in each controller initializer:

```
<?php

class ProductsController extends ControllerBase
{

    public function initialize()
    {
        //Set the document title
        $this->tag->setTitle('Manage your product types');
        parent::initialize();
    }

    //...

}
```

Note, that the method `parent::initialize()` is also called, it adds more data to the title:

```
<?php

use Phalcon\Mvc\Controller;

class ControllerBase extends Controller
{

    protected function initialize()
    {
        //Prepend the application name to the title
        $this->tag->prependTitle('INVO | ');
    }

    //...
}
```

Finally, the title is printed in the main view (`app/views/index.phtml`):

```
<!DOCTYPE html>
<html>
    <head>
        <?php echo $this->tag->getTitle() ?>
    </head>
    <!-- ... -->
</html>
```

2.7 Tutorial 6: Vökuró

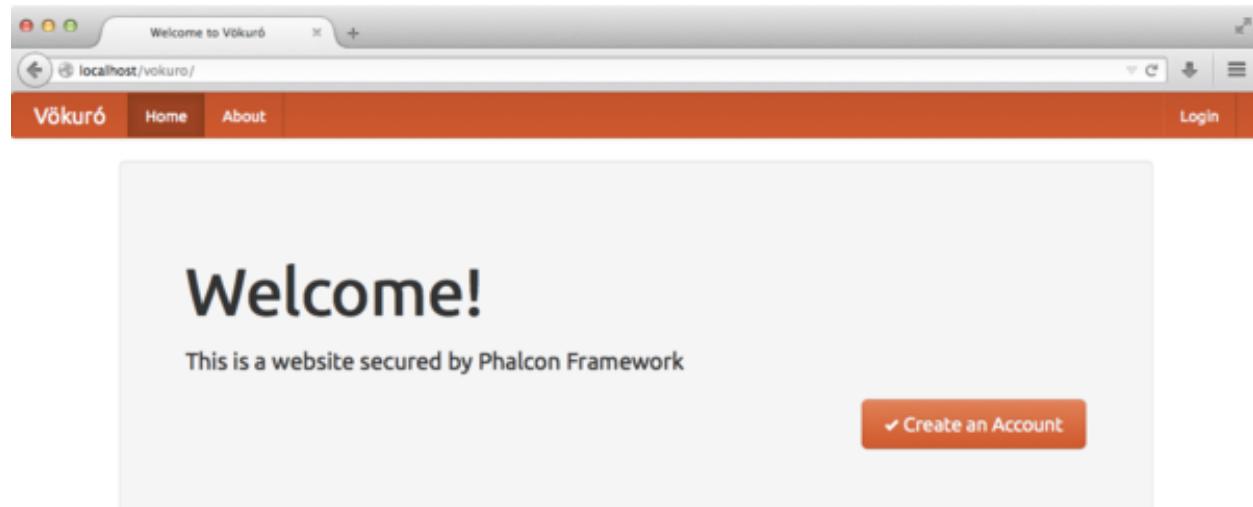

Vökuró is another sample application you can use to learn more about Phalcon. Vökuró is a small website that shows how to implement a security features and management of users and permissions. You can clone its code from [Github](#).

2.7.1 Project Structure

Once you clone the project in your document root you'll see the following structure:

```
invo/
  app/
    cache/
    config/
    controllers/
    forms/
    library/
    models/
    plugins/
    views/
  public/
    css/
    js/
  schemas/
```

This project follows a quite similar structure to INVO. Once you open the application in your browser <http://localhost/vokuro> you'll see something like this:

The screenshot shows a web browser window with the title "Welcome to Vökurö". The address bar displays "localhost/vokuro/". The page has a header with a "Vökurö" logo and navigation links for "Home", "About", and "Login". The main content area features a large "Welcome!" heading, a subtext "This is a website secured by Phalcon Framework", and a "Create an Account" button. Below this, there are three sections: "Awesome Section", "Important Stuff", and "Example addresses".

Section	Content
Awesome Section	Nullam quis risus eget urna mollis ornare vel eu leo. Cum sociis natoque penatibus et magnis dis parturient montes, nascetur ridiculus mus. Nullam id dolor id nibh ultricies vehicula ut id elit.
Important Stuff	Vivamus sagittis lacus vel augue laoreet rutrum faucibus dolor auctor. Duis mollis, est non commodo luctus, nisi erat porttitor ligula, eget lacinia odio sem nec elit. Donec sed odio dui.
Example addresses	Vokuri, Inc. 456 Infinite Loop, Suite 101 P: (123) 456-7890 Full Name vokuro@phalconphp.com

The application is divided into two parts, a frontend, where visitors can sign up the service and a backend where administrative users can manage registered users. Both frontend and backend are combined in a single module.

2.7.2 Load Classes and Dependencies

This project uses Phalcon\Loader to load controllers, models, forms, etc. within the project and composer to load the project's dependencies. So, the first thing you have to do before execute Vökuró is install its dependencies via composer. Assuming you have it correctly installed, type the following command in the console:

```
cd vokuro
composer install
```

Vökuró sends emails to confirm the sign up of registered users using Swift, the composer.json looks like:

```
{
    "require" : {
        "php" : ">=5.4.0",
        "ext-phalcon" : ">=2.0.0",
        "swiftmailer/swiftmailer" : "5.0.*",
        "amazonwebservices/aws-sdk-for-php" : "~1.0"
    }
}
```

Now, there is a file called app/config/loader.php where all the auto-loading stuff is set up. At the end of this file you can see that the composer autoloader is included enabling the application to autoload any of the classes in the downloaded dependencies:

```
<?php

// ...

// Use composer autoloader to load vendor classes
require_once __DIR__ . '/../../../vendor/autoload.php';
```

Moreover, Vökuró, unlike the INVO, utilizes namespaces for controllers and models which is the recommended practice to structure a project. This way the autoloader looks slightly different than the one we saw before (app/config/loader.php):

```
<?php

$loader = new \Phalcon\Loader();

$loader->registerNamespaces(array(
    'Vokuro\Models'      => $config->application->modelsDir,
    'Vokuro\Controllers' => $config->application->controllersDir,
    'Vokuro\Forms'        => $config->application->formsDir,
    'Vokuro'              => $config->application->libraryDir
));

$loader->register();

// ...
```

Instead of using registerDirectories, we use registerNamespaces. Every namespace points to a directory defined in the configuration file (app/config/config.php). For instance the namespace Vokuro\Controllers points to app/controllers so all the classes required by the application within this namespace requires it in its definition:

```
<?php

namespace Vokuro\Controllers;

class AboutController extends ControllerBase
```

```
{
    // ...
}
```

2.7.3 Sign Up

First, let's check how users are registered in Vökuró. When a user clicks the “Create an Account” button, the controller SessionController is invoked and the action “signup” is executed:

```
<?php

namespace Vokuro\Controllers;

use Vokuro\Forms\SignUpForm;

class RegisterController extends ControllerBase
{
    public function signupAction()
    {
        $form = new SignUpForm();

        // ...

        $this->view->form = $form;
    }
}
```

This action simply pass a form instance of SignUpForm to the view, which itself is rendered to allow the user enter the login details:

```
 {{ form('class': 'form-search') }}

<h2>Sign Up</h2>

<p> {{ form.label('name') }}</p>
<p>
    {{ form.render('name') }}
    {{ form.messages('name') }}
</p>

<p> {{ form.label('email') }}</p>
<p>
    {{ form.render('email') }}
    {{ form.messages('email') }}
</p>

<p> {{ form.label('password') }}</p>
<p>
    {{ form.render('password') }}
    {{ form.messages('password') }}
</p>

<p> {{ form.label('confirmPassword') }}</p>
<p>
    {{ form.render('confirmPassword') }}
    {{ form.messages('confirmPassword') }}
</p>
```

```
</p>

<p>
    {{ form.render('terms') }} {{ form.label('terms') }}
    {{ form.messages('terms') }}
</p>

<p>{{ form.render('Sign Up') }}</p>

{{ form.render('csrf', ['value': security.getToken()]) }}
{{ form.messages('csrf') }}

<hr>

</form>
```

2.7.4 Conclusion

As we have seen, develop a RESTful API with Phalcon is easy. Later in the documentation we'll explain in detail how to use micro applications and the [PHQL](#) language.

2.8 Tutorial 3: Creating a Simple REST API

In this tutorial, we will explain how to create a simple application that provides a **RESTful** API using the different HTTP methods:

- GET to retrieve and search data
- POST to add data
- PUT to update data
- DELETE to delete data

2.8.1 Defining the API

The API consists of the following methods:

Method	URL	Action
GET	/api/robots	Retrieves all robots
GET	/api/robots/search/Astro	Searches for robots with 'Astro' in their name
GET	/api/robots/2	Retrieves robots based on primary key
POST	/api/robots	Adds a new robot
PUT	/api/robots/2	Updates robots based on primary key
DELETE	/api/robots/2	Deletes robots based on primary key

2.8.2 Creating the Application

As the application is so simple, we will not implement any full MVC environment to develop it. In this case, we will use a [micro application](#) to meet our goal.

The following file structure is more than enough:

```
my-rest-api/
    models/
        Robots.php
    index.php
    .htaccess
```

First, we need an .htaccess file that contains all the rules to rewrite the URIs to the index.php file, that is our application:

```
<IfModule mod_rewrite.c>
    RewriteEngine On
    RewriteCond %{REQUEST_FILENAME} !-f
    RewriteRule ^(.*)$ index.php?url=/\$1 [QSA,L]
</IfModule>
```

Then, in the index.php file we create the following:

```
<?php

use Phalcon\Mvc\Micro;

$app = new Micro();

//define the routes here

$app->handle();
```

Now we will create the routes as we defined above:

```
<?php

use Phalcon\Mvc\Micro;

$app = new Micro();

//Retrieves all robots
$app->get('/api/robots', function() {

});

//Searches for robots with $name in their name
$app->get('/api/robots/search/{name}', function($name) {

});

//Retrieves robots based on primary key
$app->get('/api/robots/{id:[0-9]+}', function($id) {

});

//Adds a new robot
$app->post('/api/robots', function() {

});

//Updates robots based on primary key
$app->put('/api/robots/{id:[0-9]+}', function() {
```

```
//Deletes robots based on primary key
$app->delete('/api/robots/{id:[0-9]+}', function() {
});

$app->handle();
```

Each route is defined with a method with the same name as the HTTP method, as first parameter we pass a route pattern, followed by a handler. In this case, the handler is an anonymous function. The following route: '/api/robots/{id:[0-9]+}', by example, explicitly sets that the "id" parameter must have a numeric format.

When a defined route matches the requested URI then the application executes the corresponding handler.

2.8.3 Creating a Model

Our API provides information about 'robots', these data are stored in a database. The following model allows us to access that table in an object-oriented way. We have implemented some business rules using built-in validators and simple validations. Doing this will give us the peace of mind that saved data meet the requirements of our application:

```
<?php

use Phalcon\Mvc\Model;
use Phalcon\Mvc\Model\Message;
use Phalcon\Mvc\Model\Validator\Uniqueness;
use Phalcon\Mvc\Model\Validator\InclusionIn;

class Robots extends Model
{

    public function validation()
    {
        //Type must be: droid, mechanical or virtual
        $this->validate(new InclusionIn(
            array(
                "field" => "type",
                "domain" => array("droid", "mechanical", "virtual")
            )
        ));

        //Robot name must be unique
        $this->validate(new Uniqueness(
            array(
                "field" => "name",
                "message" => "The robot name must be unique"
            )
        ));

        //Year cannot be less than zero
        if ($this->year < 0) {
            $this->appendMessage(new Message("The year cannot be less than zero"));
        }

        //Check if any messages have been produced
        if ($this->validationHasFailed() == true) {
            return false;
        }
    }
}
```

```
}
```

Now, we must set up a connection to be used by this model and load it within our app:

```
<?php

use Phalcon\Loader;
use Phalcon\Mvc\Micro;
use Phalcon\DI\FactoryDefault;
use Phalcon\Db\Adapter\Pdo\Mysql as PdoMysql;

// Use Loader() to autoload our model
$loader = new Loader();

$loader->registerDirs(array(
    __DIR__ . '/models/'
))->register();

$di = new FactoryDefault();

//Set up the database service
$di->set('db', function() {
    return new PdoMysql(array(
        "host"      => "localhost",
        "username"  => "asimov",
        "password"  => "zeroth",
        "dbname"    => "robotics"
    ));
});

//Create and bind the DI to the application
$app = new Micro($di);
```

2.8.4 Retrieving Data

The first “handler” that we will implement is which by method GET returns all available robots. Let’s use PHQL to perform this simple query returning the results as JSON:

```
<?php

//Retrieves all robots
$app->get('/api/robots', function() use ($app) {
    $phql = "SELECT * FROM Robots ORDER BY name";
    $robots = $app->modelsManager->executeQuery($phql);

    $data = array();
    foreach ($robots as $robot) {
        $data[] = array(
            'id'      => $robot->id,
            'name'   => $robot->name,
        );
    }

    echo json_encode($data);
});
```

PHQL, allow us to write queries using a high-level, object-oriented SQL dialect that internally translates to the right SQL statements depending on the database system we are using. The clause “use” in the anonymous function allows us to pass some variables from the global to local scope easily.

The searching by name handler would look like:

```
<?php

//Searches for robots with $name in their name
$app->get('/api/robots/search/{name}', function($name) use ($app) {

    $phql = "SELECT * FROM Robots WHERE name LIKE :name: ORDER BY name";
    $robots = $app->modelsManager->executeQuery($phql, array(
        'name' => '%' . $name . '%'
    ));

    $data = array();
    foreach ($robots as $robot) {
        $data[] = array(
            'id' => $robot->id,
            'name' => $robot->name,
        );
    }

    echo json_encode($data);
});
```

Searching by the field “id” it’s quite similar, in this case, we’re also notifying if the robot was found or not:

```
<?php

use Phalcon\Http\Response;

//Retrieves robots based on primary key
$app->get('/api/robots/{id:[0-9]+}', function($id) use ($app) {

    $phql = "SELECT * FROM Robots WHERE id = :id:";
    $robot = $app->modelsManager->executeQuery($phql, array(
        'id' => $id
    ))->getFirst();

    //Create a response
    $response = new Response();

    if ($robot == false) {
        $response->setJsonContent(array('status' => 'NOT-FOUND'));
    } else {
        $response->setJsonContent(array(
            'status' => 'FOUND',
            'data' => array(
                'id' => $robot->id,
                'name' => $robot->name
            )
        ));
    }

    return $response;
});
```

2.8.5 Inserting Data

Taking the data as a JSON string inserted in the body of the request, we also use PHQL for insertion:

```
<?php

use Phalcon\Http\Response;

//Adds a new robot
$app->post('/api/robots', function() use ($app) {
    $robot = $app->request->getJsonRawBody();

    $phql = "INSERT INTO Robots (name, type, year) VALUES (:name:, :type:, :year:)";

    $status = $app->modelsManager->executeQuery($phql, array(
        'name' => $robot->name,
        'type' => $robot->type,
        'year' => $robot->year
    ));

    //Create a response
    $response = new Response();

    //Check if the insertion was successful
    if ($status->success() == true) {

        //Change the HTTP status
        $response->setStatusCode(201, "Created");

        $robot->id = $status->getModel()->id;

        $response->setJsonContent(array('status' => 'OK', 'data' => $robot));
    } else {

        //Change the HTTP status
        $response->setStatusCode(409, "Conflict");

        //Send errors to the client
        $errors = array();
        foreach ($status->getMessages() as $message) {
            $errors[] = $message->getMessage();
        }

        $response->setJsonContent(array('status' => 'ERROR', 'messages' => $errors));
    }
    return $response;
});
```

2.8.6 Updating Data

The data update is similar to insertion. The “id” passed as parameter indicates what robot must be updated:

```
<?php
```

```

use Phalcon\Http\Response;

//Updates robots based on primary key
$app->put('/api/robots/{id:[0-9]+}', function($id) use ($app) {

    $robot = $app->request->getJsonRawBody();

    $phql = "UPDATE Robots SET name = :name:, type = :type:, year = :year: WHERE id = :id:";
    $status = $app->modelsManager->executeQuery($phql, array(
        'id' => $id,
        'name' => $robot->name,
        'type' => $robot->type,
        'year' => $robot->year
    ));

    //Create a response
    $response = new Response();

    //Check if the insertion was successful
    if ($status->success() == true) {
        $response->setJsonContent(array('status' => 'OK'));
    } else {

        //Change the HTTP status
        $response->setStatusCode(409, "Conflict");

        $errors = array();
        foreach ($status->getMessages() as $message) {
            $errors[] = $message->getMessage();
        }

        $response->setJsonContent(array('status' => 'ERROR', 'messages' => $errors));
    }

    return $response;
});

```

2.8.7 Deleting Data

The data delete is similar to update. The “id” passed as parameter indicates what robot must be deleted:

```

<?php

use Phalcon\Http\Response;

//Deletes robots based on primary key
$app->delete('/api/robots/{id:[0-9]+}', function($id) use ($app) {

    $phql = "DELETE FROM Robots WHERE id = :id:";
    $status = $app->modelsManager->executeQuery($phql, array(
        'id' => $id
    ));

    //Create a response
    $response = new Response();

    if ($status->success() == true) {

```

```

    $response->setJsonContent(array('status' => 'OK'));
} else {

    //Change the HTTP status
    $response->setStatusCode(409, "Conflict");

    $errors = array();
    foreach ($status->getMessages() as $message) {
        $errors[] = $message->getMessage();
    }

    $response->setJsonContent(array('status' => 'ERROR', 'messages' => $errors));
}

return $response;
);
}

```

2.8.8 Testing our Application

Using `curl` we'll test every route in our application verifying its proper operation:

Obtain all the robots:

```

curl -i -X GET http://localhost/my-rest-api/api/robots

HTTP/1.1 200 OK
Date: Wed, 12 Sep 2014 07:05:13 GMT
Server: Apache/2.2.22 (Unix) DAV/2
Content-Length: 117
Content-Type: text/html; charset=UTF-8

[{"id": "1", "name": "Robotina"}, {"id": "2", "name": "Astro Boy"}, {"id": "3", "name": "Terminator"}]

```

Search a robot by its name:

```

curl -i -X GET http://localhost/my-rest-api/api/robots/search/Astro

HTTP/1.1 200 OK
Date: Wed, 12 Sep 2014 07:09:23 GMT
Server: Apache/2.2.22 (Unix) DAV/2
Content-Length: 31
Content-Type: text/html; charset=UTF-8

[{"id": "2", "name": "Astro Boy"}]

```

Obtain a robot by its id:

```

curl -i -X GET http://localhost/my-rest-api/api/robots/3

HTTP/1.1 200 OK
Date: Wed, 12 Sep 2014 07:12:18 GMT
Server: Apache/2.2.22 (Unix) DAV/2
Content-Length: 56
Content-Type: text/html; charset=UTF-8

{"status": "FOUND", "data": {"id": "3", "name": "Terminator"}}

```

Insert a new robot:

```
curl -i -X POST -d '{"name":"C-3PO","type":"droid","year":1977}'  
http://localhost/my-rest-api/api/robots  
  
HTTP/1.1 201 Created  
Date: Wed, 12 Sep 2014 07:15:09 GMT  
Server: Apache/2.2.22 (Unix) DAV/2  
Content-Length: 75  
Content-Type: text/html; charset=UTF-8  
  
{ "status": "OK", "data": { "name": "C-3PO", "type": "droid", "year": 1977, "id": "4" } }
```

Try to insert a new robot with the name of an existing robot:

```
curl -i -X POST -d '{"name":"C-3PO","type":"droid","year":1977}'  
http://localhost/my-rest-api/api/robots  
  
HTTP/1.1 409 Conflict  
Date: Wed, 12 Sep 2014 07:18:28 GMT  
Server: Apache/2.2.22 (Unix) DAV/2  
Content-Length: 63  
Content-Type: text/html; charset=UTF-8  
  
{ "status": "ERROR", "messages": [ "The robot name must be unique" ] }
```

Or update a robot with an unknown type:

```
curl -i -X PUT -d '{"name":"ASIMO","type":"humanoid","year":2000}'  
http://localhost/my-rest-api/api/robots/4  
  
HTTP/1.1 409 Conflict  
Date: Wed, 12 Sep 2014 08:48:01 GMT  
Server: Apache/2.2.22 (Unix) DAV/2  
Content-Length: 104  
Content-Type: text/html; charset=UTF-8  
  
{ "status": "ERROR", "messages": [ "Value of field 'type' must be part of  
list: droid, mechanical, virtual" ] }
```

Finally, delete a robot:

```
curl -i -X DELETE http://localhost/my-rest-api/api/robots/4  
  
HTTP/1.1 200 OK  
Date: Wed, 12 Sep 2014 08:49:29 GMT  
Server: Apache/2.2.22 (Unix) DAV/2  
Content-Length: 15  
Content-Type: text/html; charset=UTF-8  
  
{ "status": "OK" }
```

2.8.9 Conclusion

As we have seen, develop a RESTful API with Phalcon is easy. Later in the documentation we'll explain in detail how to use micro applications and the [PHQL](#) language.

2.9 List of examples

Following examples are full applications you can use to learn more about Phalcon and use them as base for your own websites/applications:

2.10 Dependency Injection/Service Location

The following example is a bit lengthy, but it attempts to explain why Phalcon uses service location and dependency injection. First, let's pretend we are developing a component called `SomeComponent`. This performs a task that is not important now. Our component has some dependency that is a connection to a database.

In this first example, the connection is created inside the component. This approach is impractical; due to the fact we cannot change the connection parameters or the type of database system because the component only works as created.

```
<?php

class SomeComponent
{
    /**
     * The instantiation of the connection is hardcoded inside
     * the component, therefore it's difficult replace it externally
     * or change its behavior
     */
    public function someDbTask()
    {
        $connection = new Connection(array(
            "host"      => "localhost",
            "username"  => "root",
            "password"  => "secret",
            "dbname"    => "invo"
        ));
        // ...
    }
}

$some = new SomeComponent();
$some->someDbTask();
```

To solve this, we have created a setter that injects the dependency externally before using it. For now, this seems to be a good solution:

```
<?php

class SomeComponent
{
    protected $_connection;

    /**
     * Sets the connection externally
     */
    public function setConnection($connection)
    {
        $this->_connection = $connection;
```

```
}

public function someDbTask()
{
    $connection = $this->_connection;

    // ...
}

$some = new SomeComponent();

//Create the connection
$connection = new Connection(array(
    "host"      => "localhost",
    "username"  => "root",
    "password"  => "secret",
    "dbname"    => "invo"
));

//Inject the connection in the component
$some->setConnection($connection);

$some->someDbTask();
```

Now consider that we use this component in different parts of the application and then we will need to create the connection several times before passing it to the component. Using some kind of global registry where we obtain the connection instance and not have to create it again and again could solve this:

```
<?php

class Registry
{

    /**
     * Returns the connection
     */
    public static function getConnection()
    {
        return new Connection(array(
            "host"      => "localhost",
            "username"  => "root",
            "password"  => "secret",
            "dbname"    => "invo"
        ));
    }
}

class SomeComponent
{

    protected $_connection;

    /**
     * Sets the connection externally
     */
    public function setConnection($connection)
    {
```

```

        $this->_connection = $connection;
    }

    public function someDbTask()
    {
        $connection = $this->_connection;

        // ...
    }
}

$some = new SomeComponent();

//Pass the connection defined in the registry
$some->setConnection(Registry::getConnection());

$some->someDbTask();

```

Now, let's imagine that we must implement two methods in the component, the first always needs to create a new connection and the second always needs to use a shared connection:

```

<?php

class Registry
{

    protected static $_connection;

    /**
     * Creates a connection
     */
    protected static function _createConnection()
    {
        return new Connection(array(
            "host"      => "localhost",
            "username"  => "root",
            "password"  => "secret",
            "dbname"    => "invo"
        ));
    }

    /**
     * Creates a connection only once and returns it
     */
    public static function getSharedConnection()
    {
        if (self::$_connection===null) {
            $connection = self::_createConnection();
            self::$_connection = $connection;
        }
        return self::$_connection;
    }

    /**
     * Always returns a new connection
     */
    public static function getNewConnection()
    {

```

```
        return self::__createConnection();
    }

}

class SomeComponent
{

    protected $__connection;

    /**
     * Sets the connection externally
     */
    public function setConnection($connection)
    {
        $this->__connection = $connection;
    }

    /**
     * This method always needs the shared connection
     */
    public function someDbTask()
    {
        $connection = $this->__connection;

        // ...
    }

    /**
     * This method always needs a new connection
     */
    public function someOtherDbTask($connection)
    {
        // ...
    }
}

$some = new SomeComponent();

//This injects the shared connection
$some->setConnection(Registry::getSharedConnection());

$some->someDbTask();

//Here, we always pass a new connection as parameter
$some->someOtherDbTask(Registry::getNewConnection());
```

So far we have seen how dependency injection solved our problems. Passing dependencies as arguments instead of creating them internally in the code makes our application more maintainable and decoupled. However, in the long-term, this form of dependency injection has some disadvantages.

For instance, if the component has many dependencies, we will need to create multiple setter arguments to pass the dependencies or create a constructor that passes them many arguments, additionally creating dependencies before using the component, every time, makes our code not as maintainable as we would like:

```
<?php

//Create the dependencies or retrieve them from the registry
$connection = new Connection();
```

```

$session      = new Session();
$fileSystem   = new FileSystem();
$filter       = new Filter();
$selector     = new Selector();

//Pass them as constructor parameters
$some = new SomeComponent($connection, $session, $fileSystem, $filter, $selector);

// ... or using setters

$some->setConnection($connection);
$some->setSession($session);
$some->setFileSystem($fileSystem);
$some->setFilter($filter);
$some->setSelector($selector);

```

Think if we had to create this object in many parts of our application. In the future, if we do not require any of the dependencies, we need to go through the entire code base to remove the parameter in any constructor or setter where we injected the code. To solve this, we return again to a global registry to create the component. However, it adds a new layer of abstraction before creating the object:

```

<?php

class SomeComponent
{
    // ...

    /**
     * Define a factory method to create SomeComponent instances injecting its dependencies
     */
    public static function factory()
    {

        $connection = new Connection();
        $session   = new Session();
        $fileSystem = new FileSystem();
        $filter     = new Filter();
        $selector   = new Selector();

        return new self($connection, $session, $fileSystem, $filter, $selector);
    }
}

```

Now we find ourselves back where we started, we are again building the dependencies inside of the component! We must seek a solution that keeps us from repeatedly falling into bad practices.

A practical and elegant way to solve these problems is using a container for dependencies. The containers act as the global registry that we saw earlier. Using the container for dependencies as a bridge to obtain the dependencies allows us to reduce the complexity of our component:

```

<?php

use Phalcon\DI;

class SomeComponent
{

    protected $_di;
}

```

```
public function __construct($di)
{
    $this->_di = $di;
}

public function someDbTask()
{

    // Get the connection service
    // Always returns a new connection
    $connection = $this->_di->get('db');
}

public function someOtherDbTask()
{

    // Get a shared connection service,
    // this will return the same connection everytime
    $connection = $this->_di->getShared('db');

    //This method also requires an input filtering service
    $filter = $this->_di->get('filter');
}
}

$di = new DI();

//Register a "db" service in the container
$di->set('db', function() {
    return new Connection(array(
        "host"      => "localhost",
        "username"  => "root",
        "password"  => "secret",
        "dbname"    => "invo"
    ));
});

//Register a "filter" service in the container
$di->set('filter', function() {
    return new Filter();
});

//Register a "session" service in the container
$di->set('session', function() {
    return new Session();
});

//Pass the service container as unique parameter
$some = new SomeComponent($di);

$some->someDbTask();
```

The component can now simply access the service it requires when it needs it, if it does not require a service it is not even initialized, saving resources. The component is now highly decoupled. For example, we can replace the manner in which connections are created, their behavior or any other aspect of them and that would not affect the component.

2.10.1 Our approach

Phalcon\DI is a component implementing Dependency Injection and Location of services and it's itself a container for them.

Since Phalcon is highly decoupled, Phalcon\DI is essential to integrate the different components of the framework. The developer can also use this component to inject dependencies and manage global instances of the different classes used in the application.

Basically, this component implements the [Inversion of Control](#) pattern. Applying this, the objects do not receive their dependencies using setters or constructors, but requesting a service dependency injector. This reduces the overall complexity since there is only one way to get the required dependencies within a component.

Additionally, this pattern increases testability in the code, thus making it less prone to errors.

2.10.2 Registering services in the Container

The framework itself or the developer can register services. When a component A requires component B (or an instance of its class) to operate, it can request component B from the container, rather than creating a new instance component B.

This way of working gives us many advantages:

- We can easily replace a component with one created by ourselves or a third party.
- We have full control of the object initialization, allowing us to set these objects, as needed before delivering them to components.
- We can get global instances of components in a structured and unified way

Services can be registered using several types of definitions:

```
<?php

use Phalcon\Http\Request;

// Create the Dependency Injector Container
$di = new Phalcon\DI();

// By its class name
$di->set("request", 'Phalcon\Http\Request');

// Using an anonymous function, the instance will be lazy loaded
$di->set("request", function() {
    return new Request();
});

// Registering an instance directly
$di->set("request", new Request());

// Using an array definition
$di->set("request", array(
    "className" => 'Phalcon\Http\Request'
));
```

The array syntax is also allowed to register services:

```
<?php

use Phalcon\Http\Request;
```

```
// Create the Dependency Injector Container
$di = new Phalcon\DI();

// By its class name
$di["request"] = 'Phalcon\Http\Request';

// Using an anonymous function, the instance will be lazy loaded
$di["request"] = function() {
    return new Request();
};

// Registering an instance directly
$di["request"] = new Request();

// Using an array definition
$di["request"] = array(
    "className" => 'Phalcon\Http\Request'
);
```

In the examples above, when the framework needs to access the request data, it will ask for the service identified as ‘request’ in the container. The container in turn will return an instance of the required service. A developer might eventually replace a component when he/she needs.

Each of the methods (demonstrated in the examples above) used to set/register a service has advantages and disadvantages. It is up to the developer and the particular requirements that will designate which one is used.

Setting a service by a string is simple, but lacks flexibility. Setting services using an array offers a lot more flexibility, but makes the code more complicated. The lambda function is a good balance between the two, but could lead to more maintenance than one would expect.

Phalcon\DI offers lazy loading for every service it stores. Unless the developer chooses to instantiate an object directly and store it in the container, any object stored in it (via array, string, etc.) will be lazy loaded i.e. instantiated only when requested.

Simple Registration

As seen before, there are several ways to register services. These we call simple:

String

This type expects the name of a valid class, returning an object of the specified class, if the class is not loaded it will be instantiated using an auto-loader. This type of definition does not allow to specify arguments for the class constructor or parameters:

```
<?php

// return new Phalcon\Http\Request();
$di->set('request', 'Phalcon\Http\Request');
```

Object

This type expects an object. Due to the fact that object does not need to be resolved as it is already an object, one could say that it is not really a dependency injection, however it is useful if you want to force the returned dependency to always be the same object/value:

```
<?php

use Phalcon\Http\Request;

// return new Phalcon\Http\Request();
$di->set('request', new Request());
```

Closures/Anonymous functions

This method offers greater freedom to build the dependency as desired, however, it is difficult to change some of the parameters externally without having to completely change the definition of dependency:

```
<?php

use Phalcon\Db\Adapter\Pdo\Mysql as PdoMysql;

$di->set("db", function() {
    return new PdoMysql(array(
        "host"      => "localhost",
        "username"  => "root",
        "password"  => "secret",
        "dbname"    => "blog"
    ));
});
```

Some of the limitations can be overcome by passing additional variables to the closure's environment:

```
<?php

use Phalcon\Db\Adapter\Pdo\Mysql as PdoMysql;

//Using the $config variable in the current scope
$di->set("db", function() use ($config) {
    return new PdoMysql(array(
        "host"      => $config->host,
        "username"  => $config->username,
        "password"  => $config->password,
        "dbname"    => $config->name
    ));
});
```

Complex Registration

If it is required to change the definition of a service without instantiating/resolving the service, then, we need to define the services using the array syntax. Define a service using an array definition can be a little more verbose:

```
<?php

use Phalcon\Logger\Adapter\File as LoggerFile;

// Register a service 'logger' with a class name and its parameters
$di->set('logger', array(
    'className' => 'Phalcon\Logger\Adapter\File',
    'arguments'  => array(
        array(
            'type'  => 'parameter',
```

```

        'value' => '../apps/logs/error.log'
    )
)
));

// Using an anonymous function
$di->set('logger', function() {
    return new LoggerFile('../apps/logs/error.log');
});

```

Both service registrations above produce the same result. The array definition however, allows for alteration of the service parameters if needed:

```

<?php

// Change the service class name
$di->getService('logger')->setClassName('MyCustomLogger');

// Change the first parameter without instantiating the logger
$di->getService('logger')->setParameter(0, array(
    'type' => 'parameter',
    'value' => '../apps/logs/error.log'
));

```

In addition by using the array syntax you can use three types of dependency injection:

Constructor Injection

This injection type passes the dependencies/arguments to the class constructor. Let's pretend we have the following component:

```

<?php

namespace SomeApp;

use Phalcon\Http\Response;

class SomeComponent
{

    protected $_response;

    protected $_someFlag;

    public function __construct(Response $response, $someFlag)
    {
        $this->_response = $response;
        $this->_someFlag = $someFlag;
    }
}

```

The service can be registered this way:

```

<?php

$di->set('response', array(
    'className' => 'Phalcon\Http\Response'
));

```

```
$di->set('someComponent', array(  
    'className' => 'SomeApp\SomeComponent',  
    'arguments' => array(  
        array('type' => 'service', 'name' => 'response'),  
        array('type' => 'parameter', 'value' => true)  
    )  
) ;
```

The service “response” (Phalcon\Http\Response) is resolved to be passed as the first argument of the constructor, while the second is a boolean value (true) that is passed as it is.

Setter Injection

Classes may have setters to inject optional dependencies, our previous class can be changed to accept the dependencies with setters:

```
<?php  
  
namespace SomeApp;  
  
use Phalcon\Http\Response;  
  
class SomeComponent  
{  
  
    protected $_response;  
  
    protected $_someFlag;  
  
    public function setResponse(Response $response)  
    {  
        $this->_response = $response;  
    }  
  
    public function setFlag($someFlag)  
    {  
        $this->_someFlag = $someFlag;  
    }  
}
```

A service with setter injection can be registered as follows:

```
<?php  
  
$di->set('response', array(  
    'className' => 'Phalcon\Http\Response'  
) );  
  
$di->set('someComponent', array(  
    'className' => 'SomeApp\SomeComponent',  
    'calls' => array(  
        array(  
            'method' => 'setResponse',  
            'arguments' => array(  
                array('type' => 'service', 'name' => 'response'),  
            )  
        ),  
    ),
```

```
        array(  
            'method'    => 'setFlag',  
            'arguments' => array(  
                array('type' => 'parameter', 'value' => true)  
            )  
        )  
    )  
) ;
```

Properties Injection

A less common strategy is to inject dependencies or parameters directly into public attributes of the class:

```
<?php  
  
namespace SomeApp;  
  
use Phalcon\Http\Response;  
  
class SomeComponent  
{  
  
    public $response;  
  
    public $someFlag;  
}
```

A service with properties injection can be registered as follows:

```
<?php  
  
$di->set('response', array(  
    'className' => 'Phalcon\Http\Response'  
) );  
  
$di->set('someComponent', array(  
    'className'      => 'SomeApp\SomeComponent',  
    'properties'     => array(  
        array(  
            'name'  => 'response',  
            'value' => array('type' => 'service', 'name' => 'response')  
        ),  
        array(  
            'name'  => 'someFlag',  
            'value' => array('type' => 'parameter', 'value' => true)  
        )  
    )  
) ;
```

Supported parameter types include the following:

Type	Description	Example
parameter	Represents a literal value to be passed as parameter	array('type' => 'parameter', 'value' => 1234)
service	Represents another service in the service container	array('type' => 'service', 'name' => 'request')
instance	Represents an object that must be built dynamically	array('type' => 'instance', 'className' => 'DateTime', 'arguments' => array('now'))

Resolving a service whose definition is complex may be slightly slower than simple definitions seen previously. However, these provide a more robust approach to define and inject services.

Mixing different types of definitions is allowed, everyone can decide what is the most appropriate way to register the services according to the application needs.

2.10.3 Resolving Services

Obtaining a service from the container is a matter of simply calling the “get” method. A new instance of the service will be returned:

```
<?php $request = $di->get("request");
```

Or by calling through the magic method:

```
<?php
$request = $di->getRequest();
```

Or using the array-access syntax:

```
<?php
$request = $di['request'];
```

Arguments can be passed to the constructor by adding an array parameter to the method “get”:

```
<?php
// new MyComponent("some-parameter", "other")
$component = $di->get("MyComponent", array("some-parameter", "other"));
```

Phalcon\Di is able to send events to an [EventsManager](#) if it is present. Events are triggered using the type “di”. Some events when returning boolean false could stop the active operation. The following events are supported:

Event Name	Triggered	Can stop operation?	Triggered on
beforeServiceResolve	Triggered before resolve service. Listeners receive the service name and the parameters passed to it.	No	Listeners
afterServiceResolve	Triggered after resolve service. Listeners receive the service name, instance, and the parameters passed to it.	No	Listeners

2.10.4 Shared services

Services can be registered as “shared” services this means that they always will act as singletons. Once the service is resolved for the first time the same instance of it is returned every time a consumer retrieve the service from the container:

```
<?php

use Phalcon\Session\Adapter\Files as SessionFiles;

//Register the session service as "always shared"
$di->setShared('session', function() {
    $session = new SessionFiles();
    $session->start();
    return $session;
});

$session = $di->get('session'); // Locates the service for the first time
$session = $di->getSession(); // Returns the first instantiated object
```

An alternative way to register shared services is to pass “true” as third parameter of “set”:

```
<?php

//Register the session service as "always shared"
$di->set('session', function() {
    //...
}, true);
```

If a service isn’t registered as shared and you want to be sure that a shared instance will be accessed every time the service is obtained from the DI, you can use the ‘getShared’ method:

```
<?php

$request = $di->getShared("request");
```

2.10.5 Manipulating services individually

Once a service is registered in the service container, you can retrieve it to manipulate it individually:

```
<?php

use Phalcon\Http\Request;

//Register the "register" service
$di->set('request', 'Phalcon\Http\Request');

//Get the service
$requestService = $di->getService('request');

//Change its definition
$requestService->setDefinition(function() {
    return new Request();
});

//Change it to shared
$requestService->setShared(true);

//Resolve the service (return a Phalcon\Http\Request instance)
$request = $requestService->resolve();
```

2.10.6 Instantiating classes via the Service Container

When you request a service to the service container, if it can't find out a service with the same name it'll try to load a class with the same name. With this behavior we can replace any class by another simply by registering a service with its name:

```
<?php

//Register a controller as a service
$di->set('IndexController', function() {
    $component = new Component();
    return $component;
}, true);

//Register a controller as a service
$di->set('MyOtherComponent', function() {
    //Actually returns another component
    $component = new AnotherComponent();
    return $component;
});

//Create an instance via the service container
$myComponent = $di->get('MyOtherComponent');
```

You can take advantage of this, always instantiating your classes via the service container (even if they aren't registered as services). The DI will fallback to a valid autoloader to finally load the class. By doing this, you can easily replace any class in the future by implementing a definition for it.

2.10.7 Automatic Injecting of the DI itself

If a class or component requires the DI itself to locate services, the DI can automatically inject itself to the instances it creates, to do this, you need to implement the `Phalcon\DI\InjectionAwareInterface` in your classes:

```
<?php

use Phalcon\DI\InjectionAwareInterface;

class MyClass implements InjectionAwareInterface
{

    protected $_di;

    public function setDi($di)
    {
        $this->_di = $di;
    }

    public function getDi()
    {
        return $this->_di;
    }
}
```

Then once the service is resolved, the `$di` will be passed to `setDi` automatically:

```
<?php

//Register the service
$di->set('myClass', 'MyClass');

//Resolve the service (NOTE: $myClass->setDi($di) is automatically called)
$myClass = $di->get('myClass');
```

2.10.8 Avoiding service resolution

Some services are used in each of the requests made to the application, eliminate the process of resolving the service could add some small improvement in performance.

```
<?php

//Resolve the object externally instead of using a definition for it:
$route = new MyRouter();

//Pass the resolved object to the service registration
$di->set('router', $route);
```

2.10.9 Organizing services in files

You can better organize your application by moving the service registration to individual files instead of doing everything in the application's bootstrap:

```
<?php

$di->set('router', function() {
    return include "../app/config/routes.php";
});
```

Then in the file ("..../app/config/routes.php") return the object resolved:

```
<?php

$route = new MyRouter();

$route->post('/login');

return $route;
```

2.10.10 Accessing the DI in a static way

If needed you can access the latest DI created in a static function in the following way:

```
<?php

use Phalcon\DI;

class SomeComponent
{

    public static function someMethod()
```

```
{  
    //Get the session service  
    $session = DI::getDefault()->getSession();  
}  
}
```

2.10.11 Factory Default DI

Although the decoupled character of Phalcon offers us great freedom and flexibility, maybe we just simply want to use it as a full-stack framework. To achieve this, the framework provides a variant of Phalcon\DI called Phalcon\DI\FactoryDefault. This class automatically registers the appropriate services bundled with the framework to act as full-stack.

```
<?php  
  
use Phalcon\DI\FactoryDefault;  
  
$di = new FactoryDefault();
```

2.10.12 Service Name Conventions

Although you can register services with the names you want, Phalcon has a several naming conventions that allow it to get the the correct (built-in) service when you need it.

Service Name	Description	Default	Shared
dispatcher	Controllers Dispatching Service	Phalcon\Mvc\Dispatcher	Yes
router	Routing Service	Phalcon\Mvc\Router	Yes
url	URL Generator Service	Phalcon\Mvc\Url	Yes
request	HTTP Request Environment Service	Phalcon\Http\Request	Yes
response	HTTP Response Environment Service	Phalcon\Http\Response	Yes
cookies	HTTP Cookies Management Service	Phalcon\Http\Response\Cookie	Yes
filter	Input Filtering Service	Phalcon\Filter	Yes
flash	Flash Messaging Service	Phalcon\Flash\Direct	Yes
flashSession	Flash Session Messaging Service	Phalcon\Flash\Session	Yes
session	Session Service	Phalcon\Session\Adapter\Files	Yes
eventsManager	Events Management Service	Phalcon\Events\Manager	Yes
db	Low-Level Database Connection Service	Phalcon\Db	Yes
security	Security helpers	Phalcon\Security	Yes
crypt	Encrypt/Decrypt data	Phalcon\Crypt	Yes
tag	HTML generation helpers	Phalcon\Tag	Yes
escaper	Contextual Escaping	Phalcon\Escaper	Yes
annotations	Annotations Parser	Phalcon\Annotations\Adapter\Memory	Yes
modelsManager	Models Management Service	Phalcon\Mvc\Model\Manager	Yes
modelsMetadata	Models Meta-Data Service	Phalcon\Mvc\Model\MetaData	Yes
transactionManager	Models Transaction Manager Service	Phalcon\Mvc\Model\Transaction	Yes Manager
modelsCache	Cache backend for models cache	None	•
viewsCache	Cache backend for views fragments	None	•

2.10.13 Implementing your own DI

The `Phalcon\DiInterface` interface must be implemented to create your own DI replacing the one provided by Phalcon or extend the current one.

2.11 The MVC Architecture

Phalcon offers the object-oriented classes, necessary to implement the Model, View, Controller architecture (often referred to as **MVC**) in your application. This design pattern is widely used by other web frameworks and desktop applications.

MVC benefits include:

- Isolation of business logic from the user interface and the database layer
- Making it clear where different types of code belong for easier maintenance

If you decide to use MVC, every request to your application resources will be managed by the [MVC](#) architecture. Phalcon classes are written in C language, offering a high performance approach of this pattern in a PHP based application.

2.11.1 Models

A model represents the information (data) of the application and the rules to manipulate that data. Models are primarily used for managing the rules of interaction with a corresponding database table. In most cases, each table in your database will correspond to one model in your application. The bulk of your application's business logic will be concentrated in the models. [Learn more](#)

2.11.2 Views

Views represent the user interface of your application. Views are often HTML files with embedded PHP code that perform tasks related solely to the presentation of the data. Views handle the job of providing data to the web browser or other tool that is used to make requests from your application. [Learn more](#)

2.11.3 Controllers

The controllers provide the “flow” between models and views. Controllers are responsible for processing the incoming requests from the web browser, interrogating the models for data, and passing that data on to the views for presentation. [Learn more](#)

2.12 Using Controllers

The controllers provide a number of methods that are called actions. Actions are methods on a controller that handle requests. By default all public methods on a controller map to actions and are accessible by an URL. Actions are responsible for interpreting the request and creating the response. Usually responses are in the form of a rendered view, but there are other ways to create responses as well.

For instance, when you access an URL like this: <http://localhost/blog/posts/show/2015/the-post-title> Phalcon by default will decompose each part like this:

Phalcon Directory	blog
Controller	posts
Action	show
Parameter	2015
Parameter	the-post-title

In this case, the PostsController will handle this request. There is no a special location to put controllers in an application, they could be loaded using [autoloaders](#), so you're free to organize your controllers as you need.

Controllers must have the suffix “Controller” while actions the suffix “Action”. A sample of a controller is as follows:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
}
```

```
{  
}  
  
public function showAction($year, $postTitle)  
{  
}  
}  
}
```

Additional URI parameters are defined as action parameters, so that they can be easily accessed using local variables. A controller can optionally extend `Phalcon\Mvc\Controller`. By doing this, the controller can have easy access to the application services.

Parameters without a default value are handled as required. Setting optional values for parameters is done as usual in PHP:

```
<?php  
  
use Phalcon\Mvc\Controller;  
  
class PostsController extends Controller  
{  
  
    public function indexAction()  
    {  
    }  
  
    public function showAction($year = 2012, $postTitle = 'some default title')  
    {  
    }  
}
```

Parameters are assigned in the same order as they were passed in the route. You can get an arbitrary parameter from its name in the following way:

```
<?php  
  
use Phalcon\Mvc\Controller;  
  
class PostsController extends Controller  
{  
  
    public function indexAction()  
    {  
    }  
  
    public function showAction()  
    {  
        $year      = $this->dispatcher->getParam('year');  
        $postTitle = $this->dispatcher->getParam('postTitle');  
    }  
}
```

2.12.1 Dispatch Loop

The dispatch loop will be executed within the Dispatcher until there are no actions left to be executed. In the above example only one action was executed. Now we'll see how "forward" can provide a more complex flow of operation in the dispatch loop, by forwarding execution to a different controller/action.

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function showAction($year, $postTitle)
    {
        $this->flash->error("You don't have permission to access this area");

        // Forward flow to another action
        $this->dispatcher->forward(array(
            "controller" => "users",
            "action"      => "signin"
        ));
    }
}
```

If users don't have permissions to access a certain action then will be forwarded to the Users controller, signin action.

```
<?php

use Phalcon\Mvc\Controller;

class UsersController extends Controller
{

    public function indexAction()
    {

    }

    public function signinAction()
    {

    }
}
```

There is no limit on the "forwards" you can have in your application, so long as they do not result in circular references, at which point your application will halt. If there are no other actions to be dispatched by the dispatch loop, the dispatcher will automatically invoke the view layer of the MVC that is managed by [Phalcon\Mvc\View](#).

2.12.2 Initializing Controllers

[Phalcon\Mvc\Controller](#) offers the initialize method, which is executed first, before any action is executed on a controller. The use of the "__construct" method is not recommended.

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public $settings;

    public function initialize()
    {
        $this->settings = array(
            "mySetting" => "value"
        );
    }

    public function saveAction()
    {
        if ($this->settings["mySetting"] == "value") {
            //...
        }
    }
}
```

Method ‘initialize’ is only called if the event ‘beforeExecuteRoute’ is executed with success. This avoid that application logic in the initializer cannot be executed without authorization.

If you want to execute some initialization logic just after build the controller object you can implement the method ‘onConstruct’:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function onConstruct()
    {
        //...
    }
}
```

Be aware that method ‘onConstruct’ is executed even if the action to be executed not exists in the controller or the user does not have access to it (according to custom control access provided by developer).

2.12.3 Injecting Services

If a controller extends `Phalcon\Mvc\Controller` then it has easy access to the service container in application. For example, if we have registered a service like this:

```
<?php

use Phalcon\DI;

$di = new DI();

$di->set('storage', function() {
```

```
    return new Storage('/some/directory');
}, true);
```

Then, we can access to that service in several ways:

```
<?php

use Phalcon\Mvc\Controller;

class FilesController extends Controller
{

    public function saveAction()
    {

        // Injecting the service by just accessing the property with the same name
        $this->storage->save('/some/file');

        // Accessing the service from the DI
        $this->di->get('storage')->save('/some/file');

        // Another way to access the service using the magic getter
        $this->di->getStorage()->save('/some/file');

        // Another way to access the service using the magic getter
        $this->getDi()->getStorage()->save('/some/file');

        // Using the array-syntax
        $this->di['storage']->save('/some/file');
    }
}
```

If you're using Phalcon as a full-stack framework, you can read the services provided [by default](#) in the framework.

2.12.4 Request and Response

Assuming that the framework provides a set of pre-registered services. We explain how to interact with the HTTP environment. The “request” service contains an instance of `Phalcon\Http\Request` and the “response” contains a `Phalcon\Http\Response` representing what is going to be sent back to the client.

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function saveAction()
    {
        // Check if request has made with POST
        if ($this->request->isPost() == true) {
            // Access POST data
        }
    }
}
```

```
        $customerName = $this->request->getPost("name");
        $customerBorn = $this->request->getPost("born");
    }
}
}
```

The response object is not usually used directly, but is built up before the execution of the action, sometimes - like in an afterDispatch event - it can be useful to access the response directly:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function notFoundAction()
    {
        // Send a HTTP 404 response header
        $this->response->setStatusCode(404, "Not Found");
    }
}
```

Learn more about the HTTP environment in their dedicated articles [request](#) and [response](#).

2.12.5 Session Data

Sessions help us maintain persistent data between requests. You could access a [Phalcon\Session\Bag](#) from any controller to encapsulate data that need to be persistent.

```
<?php

use Phalcon\Mvc\Controller;

class UserController extends Controller
{

    public function indexAction()
    {
        $this->persistent->name = "Michael";
    }

    public function welcomeAction()
    {
        echo "Welcome, ", $this->persistent->name;
    }
}
```

2.12.6 Using Services as Controllers

Services may act as controllers, controllers classes are always requested from the services container. Accordingly, any other class registered with its name can easily replace a controller:

```
<?php

//Register a controller as a service
$di->set('IndexController', function() {
    $component = new Component();
    return $component;
});

//Register a namespaced controller as a service
$di->set('Backend\Controllers\IndexController', function() {
    $component = new Component();
    return $component;
});
```

2.12.7 Creating a Base Controller

Some application features like access control lists, translation, cache, and template engines are often common to many controllers. In cases like these the creation of a “base controller” is encouraged to ensure your code stays **DRY**. A base controller is simply a class that extends the [Phalcon\Mvc\Controller](#) and encapsulates the common functionality that all controllers must have. In turn, your controllers extend the “base controller” and have access to the common functionality.

This class could be located anywhere, but for organizational conventions we recommend it to be in the controllers folder, e.g. apps/controllers/ControllerBase.php. We may require this file directly in the bootstrap file or cause to be loaded using any autoloader:

```
<?php

require "../app/controllers/ControllerBase.php";
```

The implementation of common components (actions, methods, properties etc.) resides in this file:

```
<?php

use Phalcon\Mvc\Controller;

class ControllerBase extends Controller
{

    /**
     * This action is available for multiple controllers
     */
    public function someAction()
    {

    }
}
```

Any other controller now inherits from ControllerBase, automatically gaining access to the common components (discussed above):

```
<?php

class UsersController extends ControllerBase
{

}
```

2.12.8 Events in Controllers

Controllers automatically act as listeners for dispatcher events, implementing methods with those event names allow you to implement hook points before/after the actions are executed:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function beforeExecuteRoute($dispatcher)
    {
        // This is executed before every found action
        if ($dispatcher->getActionName() == 'save') {

            $this->flash->error("You don't have permission to save posts");

            $this->dispatcher->forward(array(
                'controller' => 'home',
                'action'      => 'index'
            ));

            return false;
        }
    }

    public function afterExecuteRoute($dispatcher)
    {
        // Executed after every found action
    }
}
```

2.13 Working with Models

A model represents the information (data) of the application and the rules to manipulate that data. Models are primarily used for managing the rules of interaction with a corresponding database table. In most cases, each table in your database will correspond to one model in your application. The bulk of your application's business logic will be concentrated in the models.

`Phalcon\Mvc\Model` is the base for all models in a Phalcon application. It provides database independence, basic CRUD functionality, advanced finding capabilities, and the ability to relate models to one another, among other services. `Phalcon\Mvc\Model` avoids the need of having to use SQL statements because it translates methods dynamically to the respective database engine operations.

Models are intended to work on a database high layer of abstraction. If you need to work with databases at a lower level check out the `Phalcon\Db` component documentation.

2.13.1 Creating Models

A model is a class that extends from `Phalcon\Mvc\Model`. It must be placed in the models directory. A model file must contain a single class; its class name should be in camel case notation:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{
```

The above example shows the implementation of the “Robots” model. Note that the class `Robots` inherits from `Phalcon\Mvc\Model`. This component provides a great deal of functionality to models that inherit it, including basic database CRUD (Create, Read, Update, Delete) operations, data validation, as well as sophisticated search support and the ability to relate multiple models with each other.

If you’re using PHP 5.4/5.5 it is recommended you declare each column that makes part of the model in order to save memory and reduce the memory allocation.

By default, the model “Robots” will refer to the table “`robots`”. If you want to manually specify another name for the mapping table, you can use the `getSource()` method:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public function getSource()
    {
        return "the_robots";
    }
}
```

The model `Robots` now maps to “`the_robots`” table. The `initialize()` method aids in setting up the model with a custom behavior i.e. a different table. The `initialize()` method is only called once during the request.

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public function initialize()
    {
        $this->setSource("the_robots");
    }
}
```

The `initialize()` method is only called once during the request, it’s intended to perform initializations that apply for all instances of the model created within the application. If you want to perform initialization tasks for every instance created you can ‘`onConstruct`’:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public function onConstruct()
    {
        //...
    }
}
```

Public properties vs. Setters/Getters

Models can be implemented with properties of public scope, meaning that each property can be read/updated from any part of the code that has instantiated that model class without any restrictions:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{
    public $id;
    public $name;
    public $price;
}
```

By using getters and setters you can control which properties are visible publicly perform various transformations to the data (which would be impossible otherwise) and also add validation rules to the data stored in the object:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{
    protected $id;
    protected $name;
    protected $price;

    public function getId()
    {
        return $this->id;
    }

    public function setName($name)
    {
        // The name is too short?
        if (strlen($name) < 10) {
            throw new \InvalidArgumentException('The name is too short');
        }
    }
}
```

```

        $this->name = $name;
    }

    public function getName()
    {
        return $this->name;
    }

    public function setPrice($price)
    {
        // Negative prices aren't allowed
        if ($price < 0) {
            throw new \InvalidArgumentException('Price can\'t be negative');
        }
        $this->price = $price;
    }

    public function getPrice()
    {
        // Convert the value to double before be used
        return (double) $this->price;
    }
}

```

Public properties provide less complexity in development. However getters/setters can heavily increase the testability, extensibility and maintainability of applications. Developers can decide which strategy is more appropriate for the application they are creating. The ORM is compatible with both schemes of defining properties.

Models in Namespaces

Namespaces can be used to avoid class name collision. The mapped table is taken from the class name, in this case ‘Robots’:

```

<?php

namespace Store\Toys;

use Phalcon\Mvc\Model;

class Robots extends Model
{
    // ...
}

```

Namespaces make part of model names when they are within strings:

```

<?php

namespace Store\Toys;

use Phalcon\Mvc\Model;

class Robots extends Model
{
    public $id;

    public $name;
}

```

```
public function initialize()
{
    $this->hasMany('id', 'Store\Toys\RobotsParts', 'robots_id');
}
```

2.13.2 Understanding Records To Objects

Every instance of a model represents a row in the table. You can easily access record data by reading object properties. For example, for a table “robots” with the records:

```
mysql> select * from robots;
+----+-----+-----+-----+
| id | name      | type       | year |
+----+-----+-----+-----+
| 1  | Robotina   | mechanical | 1972 |
| 2  | Astro Boy  | mechanical | 1952 |
| 3  | Terminator | cyborg     | 2029 |
+----+-----+-----+-----+
3 rows in set (0.00 sec)
```

You could find a certain record by its primary key and then print its name:

```
<?php

// Find record with id = 3
$robot = Robots::findFirst(3);

// Prints "Terminator"
echo $robot->name;
```

Once the record is in memory, you can make modifications to its data and then save changes:

```
<?php

$robot      = Robots::findFirst(3);
$robot->name = "RoboCop";
$robot->save();
```

As you can see, there is no need to use raw SQL statements. `Phalcon\Mvc\Model` provides high database abstraction for web applications.

2.13.3 Finding Records

`Phalcon\Mvc\Model` also offers several methods for querying records. The following examples will show you how to query one or more records from a model:

```
<?php

// How many robots are there?
$robots = Robots::find();
echo "There are ", count($robots), "\n";

// How many mechanical robots are there?
$robots = Robots::find("type = 'mechanical'");
echo "There are ", count($robots), "\n";
```

```
// Get and print virtual robots ordered by name
$robots = Robots::find(array(
    "type" = 'virtual',
    "order" => "name"
));
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}

// Get first 100 virtual robots ordered by name
$robots = Robots::find(array(
    "type" = 'virtual',
    "order" => "name",
    "limit" => 100
));
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}
```

If you want find record by external data (such as user input) or variable data you must use *Binding Parameters*.

You could also use the `findFirst()` method to get only the first record matching the given criteria:

```
<?php

// What's the first robot in robots table?
$robot = Robots::findFirst();
echo "The robot name is ", $robot->name, "\n";

// What's the first mechanical robot in robots table?
$robot = Robots::findFirst("type = 'mechanical'");
echo "The first mechanical robot name is ", $robot->name, "\n";

// Get first virtual robot ordered by name
$robot = Robots::findFirst(array("type = 'virtual'", "order" => "name"));
echo "The first virtual robot name is ", $robot->name, "\n";
```

Both `find()` and `findFirst()` methods accept an associative array specifying the search criteria:

```
<?php

$robot = Robots::findFirst(array(
    "type" = 'virtual',
    "order" => "name DESC",
    "limit" => 30
));

$robots = Robots::find(array(
    "conditions" => "type = ?1",
    "bind"        => array(1 => "virtual")
));
```

The available query options are:

Parameter	Description	Example
conditions	Search conditions for the find operation. Is used to extract only those records that fulfill a specified criterion. By default Phalcon\Mvc\Model assumes the first parameter are the conditions.	“conditions” => “name LIKE ‘steve%'”
columns	Return specific columns instead of the full columns in the model. When using this option an incomplete object is returned	“columns” => “id, name”
bind	Bind is used together with options, by replacing placeholders and escaping values thus increasing security	“bind” => array(“status” => “A”, “type” => “some-time”)
bindTypes	When binding parameters, you can use this parameter to define additional casting to the bound parameters increasing even more the security	“bindTypes” => array(Column::BIND_PARAM_STR, Column::BIND_PARAM_INT)
order	Is used to sort the resultset. Use one or more fields separated by commas.	“order” => “name DESC, status”
limit	Limit the results of the query to results to certain range	“limit” => 10 / “limit” => array(“number” => 10, “offset” => 5)
group	Allows to collect data across multiple records and group the results by one or more columns	“group” => “name, status”
for_update	With this option, Phalcon\Mvc\Model reads the latest available data, setting exclusive locks on each row it reads	“for_update” => true
shared_lock	With this option, Phalcon\Mvc\Model reads the latest available data, setting shared locks on each row it reads	“shared_lock” => true
cache	Cache the resultset, reducing the continuous access to the relational system	“cache” => array(“lifetime” => 3600, “key” => “my-find-key”)
hydration	Sets the hydration strategy to represent each returned record in the result	“hydration” => Resultset::HYDRATE_OBJECTS

If you prefer, there is also available a way to create queries in an object-oriented way, instead of using an array of parameters:

```
<?php

$robots = Robots::query()
    ->where("type = :type:")
    ->andWhere("year < 2000")
    ->bind(array("type" => "mechanical"))
    ->order("name")
    ->execute();
```

The static method `query()` returns a `Phalcon\Mvc\Model\Criteria` object that is friendly with IDE autocompleters.

All the queries are internally handled as `PHQL` queries. `PHQL` is a high-level, object-oriented and SQL-like language. This language provide you more features to perform queries like joining other models, define groupings, add aggregations etc.

Lastly, there is the `findFirstBy<property-name>()` method. This method expands on the “`findFirst()`” method mentioned earlier. It allows you to quickly perform a retrieval from a table by using the property name in the method itself and passing it a parameter that contains the data you want to search for in that column. An example is in order, so taking our `Robots` model mentioned earlier :

```
<?php

use Phalcon\Mvc\Model;
```

```
class Robots extends Model
{
    public $id;
    public $name;
    public $price;
}
```

We have three properties to work with here. \$id, \$name and \$price. So, let's say you want to retrieve the first record in the table with the name 'Terminator'. This could be written like:

```
<?php

$name = "Terminator";
$robot = Robots::findFirstByName($name);

if ($robot) {
    echo "The first robot with the name " . $name . " cost " . $robot->price . ".";
} else {
    echo "There were no robots found in our table with the name " . $name . ".";
}
```

Notice that we used 'Name' in the method call and passed the variable \$name to it, which contains the name we are looking for in our table. Notice also that when we find a match with our query, all the other properties are available to us as well.

Model Resultsets

While `findFirst()` returns directly an instance of the called class (when there is data to be returned), the `find()` method returns a `Phalcon\Mvc\Model\ResultsetSimple`. This is an object that encapsulates all the functionality a resultset has like traversing, seeking specific records, counting, etc.

These objects are more powerful than standard arrays. One of the greatest features of the `Phalcon\Mvc\Model\Resultset` is that at any time there is only one record in memory. This greatly helps in memory management especially when working with large amounts of data.

```
<?php

// Get all robots
$robots = Robots::find();

// Traversing with a foreach
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}

// Traversing with a while
$robots->rewind();
while ($robots->valid()) {
    $robot = $robots->current();
    echo $robot->name, "\n";
    $robots->next();
}

// Count the resultset
echo count($robots);
```

```
// Alternative way to count the resultset
echo $robots->count();

// Move the internal cursor to the third robot
$robots->seek(2);
$robot = $robots->current();

// Access a robot by its position in the resultset
$robot = $robots[5];

// Check if there is a record in certain position
if (isset($robots[3])) {
    $robot = $robots[3];
}

// Get the first record in the resultset
$robot = $robots->getFirst();

// Get the last record
$robot = $robots->getLast();
```

Phalcon's resultsets emulate scrollable cursors, you can get any row just by accessing its position, or seeking the internal pointer to a specific position. Note that some database systems don't support scrollable cursors, this forces to re-execute the query in order to rewind the cursor to the beginning and obtain the record at the requested position. Similarly, if a resultset is traversed several times, the query must be executed the same number of times.

Storing large query results in memory could consume many resources, because of this, resultsets are obtained from the database in chunks of 32 rows reducing the need for re-execute the request in several cases also saving memory.

Note that resultsets can be serialized and stored in a cache backend. [Phalcon\Cache](#) can help with that task. However, serializing data causes [Phalcon\Mvc\Model](#) to retrieve all the data from the database in an array, thus consuming more memory while this process takes place.

```
<?php

// Query all records from model parts
$parts = Parts::find();

// Store the resultset into a file
file_put_contents("cache.txt", serialize($parts));

// Get parts from file
$parts = unserialize(file_get_contents("cache.txt"));

// Traverse the parts
foreach ($parts as $part) {
    echo $part->id;
}
```

Filtering Resultsets

The most efficient way to filter data is setting some search criteria, databases will use indexes set on tables to return data faster. Phalcon additionally allows you to filter the data using PHP using any resource that is not available in the database:

```
<?php
```

```
$customers = Customers::find()->filter(function($customer) {
    // Return only customers with a valid e-mail
    if (filter_var($customer->email, FILTER_VALIDATE_EMAIL)) {
        return $customer;
    }
});
```

Binding Parameters

Bound parameters are also supported in Phalcon\Mvc\Model. You are encouraged to use this methodology so as to eliminate the possibility of your code being subject to SQL injection attacks. Both string and integer placeholders are supported. Binding parameters can simply be achieved as follows:

```
<?php

// Query robots binding parameters with string placeholders
$conditions = "name = :name: AND type = :type:";

// Parameters whose keys are the same as placeholders
$parameters = array(
    "name" => "Robotina",
    "type" => "maid"
);

// Perform the query
$robots = Robots::find(array(
    $conditions,
    "bind" => $parameters
));

// Query robots binding parameters with integer placeholders
$conditions = "name = ?1 AND type = ?2";
$parameters = array(1 => "Robotina", 2 => "maid");
$robots = Robots::find(array(
    $conditions,
    "bind" => $parameters
));

// Query robots binding parameters with both string and integer placeholders
$conditions = "name = :name: AND type = ?1";

// Parameters whose keys are the same as placeholders
$parameters = array(
    "name" => "Robotina",
    1       => "maid"
);

// Perform the query
$robots = Robots::find(array(
    $conditions,
    "bind" => $parameters
));
```

When using numeric placeholders, you will need to define them as integers i.e. 1 or 2. In this case “1” or “2” are considered strings and not numbers, so the placeholder could not be successfully replaced.

Strings are automatically escaped using `PDO`. This function takes into account the connection charset, so its recommended to define the correct charset in the connection parameters or in the database configuration, as a wrong charset will produce undesired effects when storing or retrieving data.

Additionally you can set the parameter “bindTypes”, this allows defining how the parameters should be bound according to its data type:

```
<?php

use Phalcon\Db\Column;

//Bind parameters
$parameters = array(
    "name" => "Robotina",
    "year" => 2008
);

//Casting Types
$types = array(
    "name" => Column::BIND_PARAM_STR,
    "year" => Column::BIND_PARAM_INT
);

// Query robots binding parameters with string placeholders
$robots = Robots::find(array(
    "name = :name: AND year = :year:",
    "bind" => $parameters,
    "bindTypes" => $types
));
;
```

Since the default bind-type is `\Phalcon\Db\Column::BIND_PARAM_STR`, there is no need to specify the “bindTypes” parameter if all of the columns are of that type.

Bound parameters are available for all query methods such as `find()` and `findFirst()` but also the calculation methods like `count()`, `sum()`, `average()` etc.

If you’re using “finders”, bound parameters are automatically used for you:

```
<?php

// Explicit query using bound parameters
$robots = Robots::find(array(
    "name = ?0",
    "bind" => ["Ultron"],
));
;

// Implicit query using bound parameters
$robots = Robots::findByName("Ultron");
```

2.13.4 Initializing/Preparing fetched records

May be the case that after obtaining a record from the database is necessary to initialise the data before being used by the rest of the application. You can implement the method ‘`afterFetch`’ in a model, this event will be executed just after create the instance and assign the data to it:

```
<?php

use Phalcon\Mvc\Model;
```

```

class Robots extends Model
{
    public $id;
    public $name;
    public $status;

    public function beforeSave()
    {
        //Convert the array into a string
        $this->status = join(',', $this->status);
    }

    public function afterFetch()
    {
        //Convert the string to an array
        $this->status = explode(',', $this->status);
    }
}

```

If you use getters/setters instead of/and together with public properties, you can initialize the field once it is accessed:

```

<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{
    public $id;

    public $name;

    public $status;

    public function getStatus()
    {
        return explode(',', $this->status);
    }
}

```

2.13.5 Relationships between Models

There are four types of relationships: one-on-one, one-to-many, many-to-one and many-to-many. The relationship may be unidirectional or bidirectional, and each can be simple (a one to one model) or more complex (a combination of models). The model manager manages foreign key constraints for these relationships, the definition of these helps referential integrity as well as easy and fast access of related records to a model. Through the implementation of relations, it is easy to access data in related models from each record in a uniform way.

Unidirectional relationships

Unidirectional relations are those that are generated in relation to one another but not vice versa.

Bidirectional relations

The bidirectional relations build relationships in both models and each model defines the inverse relationship of the other.

Defining relationships

In Phalcon, relationships must be defined in the initialize() method of a model. The methods belongsTo(), hasOne(),hasMany() and hasManyToMany() define the relationship between one or more fields from the current model to fields in another model. Each of these methods requires 3 parameters: local fields, referenced model, referenced fields.

Method	Description
hasMany	Defines a 1-n relationship
hasOne	Defines a 1-1 relationship
belongsTo	Defines a n-1 relationship
hasManyToMany	Defines a n-n relationship

The following schema shows 3 tables whose relations will serve us as an example regarding relationships:

```
CREATE TABLE `robots` (
    `id` int(10) unsigned NOT NULL AUTO_INCREMENT,
    `name` varchar(70) NOT NULL,
    `type` varchar(32) NOT NULL,
    `year` int(11) NOT NULL,
    PRIMARY KEY (`id`)
);

CREATE TABLE `robots_parts` (
    `id` int(10) unsigned NOT NULL AUTO_INCREMENT,
    `robots_id` int(10) NOT NULL,
    `parts_id` int(10) NOT NULL,
    `created_at` DATE NOT NULL,
    PRIMARY KEY (`id`),
    KEY `robots_id` (`robots_id`),
    KEY `parts_id` (`parts_id`)
);

CREATE TABLE `parts` (
    `id` int(10) unsigned NOT NULL AUTO_INCREMENT,
    `name` varchar(70) NOT NULL,
    PRIMARY KEY (`id`)
);
```

- The model “Robots” has many “RobotsParts”.
- The model “Parts” has many “RobotsParts”.
- The model “RobotsParts” belongs to both “Robots” and “Parts” models as a many-to-one relation.
- The model “Robots” has a relation many-to-many to “Parts” through “RobotsParts”

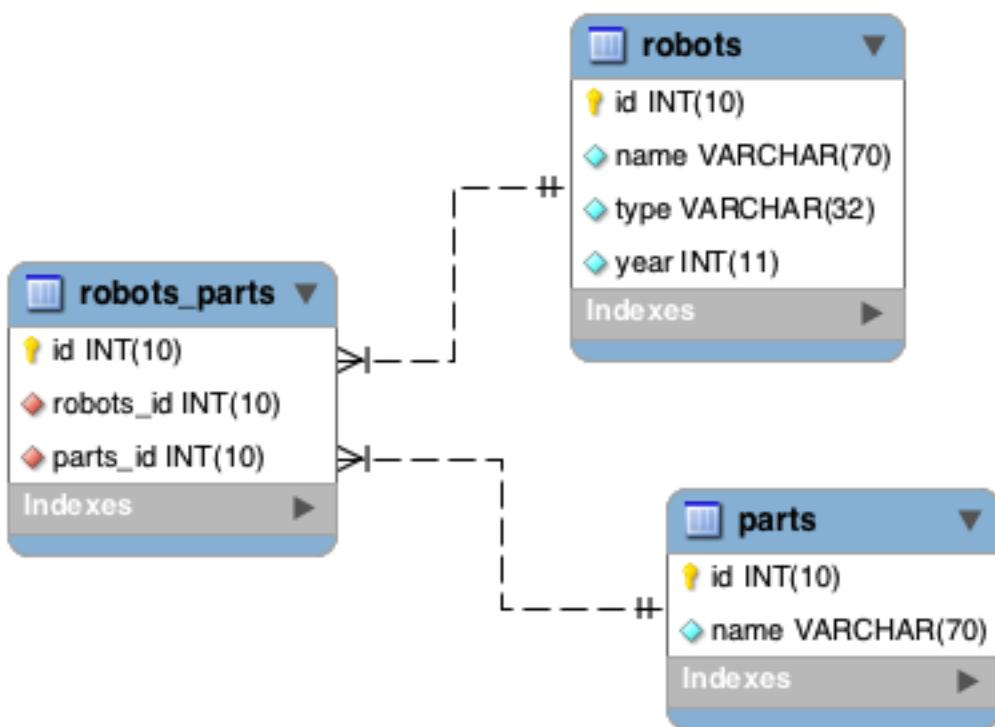

Check the EER diagram to understand better the relations:

The models with their relations could be implemented as follows:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
```

```
{
    public $id;

    public $name;

    public function initialize()
    {
        $this->hasMany("id", "RobotsParts", "robots_id");
    }
}
```

```
<?php

use Phalcon\Mvc\Model;

class Parts extends Model
{

    public $id;

    public $name;

    public function initialize()
    {
        $this->hasMany("id", "RobotsParts", "parts_id");
    }
}
```

```
<?php

use Phalcon\Mvc\Model;

class RobotsParts extends Model
{

    public $id;

    public $robots_id;

    public $parts_id;

    public function initialize()
    {
        $this->belongsTo("robots_id", "Robots", "id");
        $this->belongsTo("parts_id", "Parts", "id");
    }
}
```

The first parameter indicates the field of the local model used in the relationship; the second indicates the name of the referenced model and the third the field name in the referenced model. You could also use arrays to define multiple fields in the relationship.

Many to many relationships require 3 models and define the attributes involved in the relationship:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
```

```
{
    public $id;

    public $name;

    public function initialize()
    {
        $this->hasManyToMany(
            "id",
            "RobotsParts",
            "robots_id", "parts_id",
            "Parts",
            "id"
        );
    }
}
```

Taking advantage of relationships

When explicitly defining the relationships between models, it is easy to find related records for a particular record.

```
<?php

$robot = Robots::findFirst(2);
foreach ($robot->robotsParts as $robotPart) {
    echo $robotPart->parts->name, "\n";
}
```

Phalcon uses the magic methods `__set`/`__get`/`__call` to store or retrieve related data using relationships.

By accessing an attribute with the same name as the relationship will retrieve all its related record(s).

```
<?php

$robot = Robots::findFirst();
$robotsParts = $robot->robotsParts; // all the related records in RobotsParts
```

Also, you can use a magic getter:

```
<?php

$robot = Robots::findFirst();
$robotsParts = $robot->getRobotsParts(); // all the related records in RobotsParts
$robotsParts = $robot->getRobotsParts(array('limit' => 5)); // passing parameters
```

If the called method has a “get” prefix Phalcon\Mvc\Model will return a `findFirst()`/`find()` result. The following example compares retrieving related results with using magic methods and without:

```
<?php

$robot      = Robots::findFirst(2);

// Robots model has a 1-n (hasMany)
// relationship to RobotsParts then
$robotsParts = $robot->robotsParts;

// Only parts that match conditions
$robotsParts = $robot->getRobotsParts("created_at = '2015-03-15'");
```

```
// Or using bound parameters
$robotsParts = $robot->getRobotsParts(array(
    "created_at" = :date|,
    "bind" => array("date" => "2015-03-15")
));

$robotPart = RobotsParts::findFirst(1);

// RobotsParts model has a n-1 (belongsTo)
// relationship to RobotsParts then
$robot = $robotPart->robots;
```

Getting related records manually:

```
<?php

$robot = Robots::findFirst(2);

// Robots model has a 1-n (hasMany)
// relationship to RobotsParts, then
$robotsParts = RobotsParts::find("robots_id = '" . $robot->id . "'");

// Only parts that match conditions
$robotsParts = RobotsParts::find(
    "robots_id = '" . $robot->id . "' AND created_at = '2015-03-15'"
);

$robotPart = RobotsParts::findFirst(1);

// RobotsParts model has a n-1 (belongsTo)
// relationship to RobotsParts then
$robot = Robots::findFirst("id = '" . $robotPart->robots_id . "'");
```

The prefix “get” is used to find()/findFirst() related records. Depending on the type of relation it will use ‘find’ or ‘findFirst’:

Type	Description	Implicit Method
Belongs-To	Returns a model instance of the related record directly	findFirst
Has-One	Returns a model instance of the related record directly	findFirst
Has-Many	Returns a collection of model instances of the referenced model	find
Has-Many-to-Many	Returns a collection of model instances of the referenced model, it implicitly does ‘inner joins’ with the involved models	(complex query)

You can also use “count” prefix to return an integer denoting the count of the related records:

```
<?php

$robot = Robots::findFirst(2);
echo "The robot has ", $robot->countRobotsParts(), " parts\n";
```

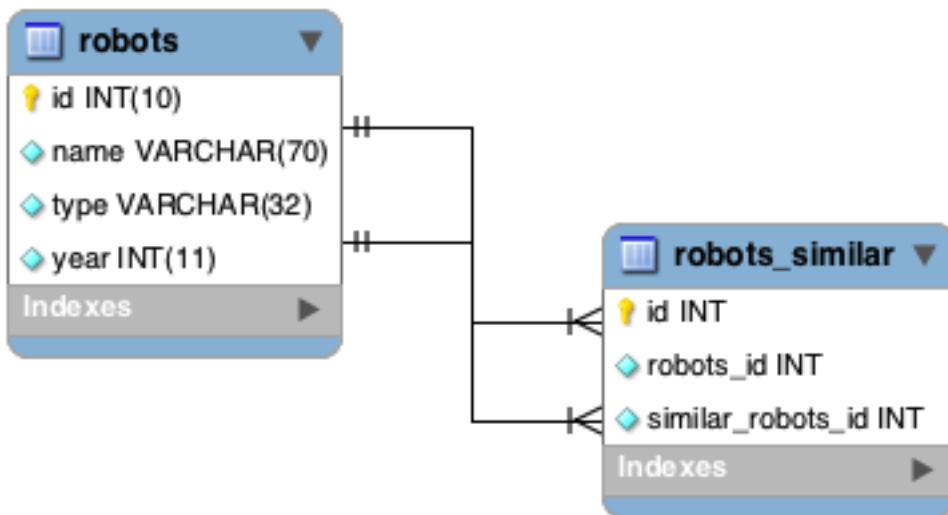

Aliasing Relationships

To explain better how aliases work, let’s check the following example:

Table “robots_similar” has the function to define what robots are similar to others:

```
mysql> desc robots_similar;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| id | int(10) unsigned | NO | PRI | NULL | auto_increment |
| robots_id | int(10) unsigned | NO | MUL | NULL | |
| similar_robots_id | int(10) unsigned | NO | | NULL | |
+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

Both “robots_id” and “similar_robots_id” have a relation to the model Robots:

A model that maps this table and its relationships is the following:

```
<?php

class RobotsSimilar extends Phalcon\Mvc\Model
{

    public function initialize()
    {
        $this->belongsTo('robots_id', 'Robots', 'id');
        $this->belongsTo('similar_robots_id', 'Robots', 'id');
    }
}
```

Since both relations point to the same model (Robots), obtain the records related to the relationship could not be clear:

```
<?php

$robotsSimilar = RobotsSimilar::findFirst();

//Returns the related record based on the column (robots_id)
//Also as is a belongsTo it's only returning one record
//but the name 'getRobots' seems to imply that return more than one
$robot = $robotsSimilar->getRobots();

//but, how to get the related record based on the column (similar_robots_id)
```

```
//if both relationships have the same name?
```

The aliases allow us to rename both relationships to solve these problems:

```
<?php

use Phalcon\Mvc\Model;

class RobotsSimilar extends Model
{

    public function initialize()
    {
        $this->belongsTo('robots_id', 'Robots', 'id', array(
            'alias' => 'Robot'
        ));
        $this->belongsTo('similar_robots_id', 'Robots', 'id', array(
            'alias' => 'SimilarRobot'
        ));
    }
}
```

With the aliasing we can get the related records easily:

```
<?php

$robotsSimilar = RobotsSimilar::findFirst();

//Returns the related record based on the column (robots_id)
$robot = $robotsSimilar->getRobot();
$robot = $robotsSimilar->robot;

//Returns the related record based on the column (similar_robots_id)
$similarRobot = $robotsSimilar->getSimilarRobot();
$similarRobot = $robotsSimilar->similarRobot;
```

Magic Getters vs. Explicit methods

Most IDEs and editors with auto-completion capabilities can not infer the correct types when using magic getters, instead of use the magic getters you can optionally define those methods explicitly with the corresponding docblocks helping the IDE to produce a better auto-completion:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public $id;
    public $name;

    public function initialize()
    {
        $this->hasMany("id", "RobotsParts", "robots_id");
    }
}
```

```

/**
 * Return the related "robots parts"
 *
 * @return \RobotsParts[]
 */
public function getRobotsParts($parameters=null)
{
    return $this->getRelated('RobotsParts', $parameters);
}

```

2.13.6 Virtual Foreign Keys

By default, relationships do not act like database foreign keys, that is, if you try to insert/update a value without having a valid value in the referenced model, Phalcon will not produce a validation message. You can modify this behavior by adding a fourth parameter when defining a relationship.

The RobotsPart model can be changed to demonstrate this feature:

```

<?php

use Phalcon\Mvc\Model;

class RobotsParts extends Model
{

    public $id;

    public $robots_id;

    public $parts_id;

    public function initialize()
    {
        $this->belongsTo("robots_id", "Robots", "id", array(
            "foreignKey" => true
        ));

        $this->belongsTo("parts_id", "Parts", "id", array(
            "foreignKey" => array(
                "message" => "The part_id does not exist on the Parts model"
            )
        ));
    }
}

```

If you alter a belongsTo() relationship to act as foreign key, it will validate that the values inserted/updated on those fields have a valid value on the referenced model. Similarly, if a hasMany()/hasOne() is altered it will validate that the records cannot be deleted if that record is used on a referenced model.

```

<?php

use Phalcon\Mvc\Model;

class Parts extends Model
{

```

```
public function initialize()
{
    $this->hasMany("id", "RobotsParts", "parts_id", array(
        "foreignKey" => array(
            "message" => "The part cannot be deleted because other robots are using it"
        )
    )));
}
```

A virtual foreign key can be set up to allow null values as follows:

```
<?php

use Phalcon\Mvc\Model;

class RobotsParts extends Model
{

    public $id;

    public $robots_id;

    public $parts_id;

    public function initialize()
    {
        $this->belongsTo("parts_id", "Parts", "id", array(
            "foreignKey" => array(
                "allowNull" => true,
                "message" => "The part_id does not exist on the Parts model"
            )
        ));
    }
}
```

Cascade/Restrict actions

Relationships that act as virtual foreign keys by default restrict the creation/update/deletion of records to maintain the integrity of data:

```
<?php

namespace Store\Models;

use Phalcon\Mvc\Model;
use Phalcon\Mvc\Model\Relation;

class Robots extends Model
{

    public $id;

    public $name;

    public function initialize()
    {
```

```

    $this->hasMany('id', 'Store\\Models\\Parts', 'robots_id', array(
        'foreignKey' => array(
            'action' => Relation::ACTION CASCADE
        )
    )));
}
}

```

The above code set up to delete all the referenced records (parts) if the master record (robot) is deleted.

2.13.7 Generating Calculations

Calculations (or aggregations) are helpers for commonly used functions of database systems such as COUNT, SUM, MAX, MIN or AVG. `Phalcon\Mvc\Model` allows to use these functions directly from the exposed methods.

Count examples:

```

<?php

// How many employees are?
$rowcount = Employees::count();

// How many different areas are assigned to employees?
$rowcount = Employees::count(array("distinct" => "area"));

// How many employees are in the Testing area?
$rowcount = Employees::count("area = 'Testing'");

// Count employees grouping results by their area
$group = Employees::count(array("group" => "area"));
foreach ($group as $row) {
    echo "There are ", $row->rowcount, " in ", $row->area;
}

// Count employees grouping by their area and ordering the result by count
$group = Employees::count(array(
    "group" => "area",
    "order" => "rowcount"
));

// Avoid SQL injections using bound parameters
$group = Employees::count(array(
    "type > ?0",
    "bind" => array($type)
));

```

Sum examples:

```

<?php

// How much are the salaries of all employees?
$total = Employees::sum(array("column" => "salary"));

// How much are the salaries of all employees in the Sales area?
$total = Employees::sum(array(
    "column"      => "salary",
    "conditions" => "area = 'Sales'"
));

```

```
// Generate a grouping of the salaries of each area
$group = Employees::sum(array(
    "column" => "salary",
    "group"  => "area"
));
foreach ($group as $row) {
    echo "The sum of salaries of the ", $row->area, " is ", $row->sumatory;
}

// Generate a grouping of the salaries of each area ordering
// salaries from higher to lower
$group = Employees::sum(array(
    "column" => "salary",
    "group"  => "area",
    "order"   => "sumatory DESC"
));

// Avoid SQL injections using bound parameters
$group = Employees::sum(array(
    "conditions" => "area > ?0",
    "bind"        => array($area)
));

```

Average examples:

```
<?php

// What is the average salary for all employees?
$average = Employees::average(array("column" => "salary"));

// What is the average salary for the Sales's area employees?
$average = Employees::average(array(
    "column"      => "salary",
    "conditions" => "area = 'Sales'"
));

// Avoid SQL injections using bound parameters
$average = Employees::average(array(
    "column"      => "age",
    "conditions" => "area > ?0",
    "bind"        => array($area)
));

```

Max/Min examples:

```
<?php

// What is the oldest age of all employees?
$age = Employees::maximum(array("column" => "age"));

// What is the oldest of employees from the Sales area?
$age = Employees::maximum(array(
    "column"      => "age",
    "conditions" => "area = 'Sales'"
));

// What is the lowest salary of all employees?
$Salary = Employees::minimum(array("column" => "salary"));

```

2.13.8 Hydration Modes

As mentioned above, resultsets are collections of complete objects, this means that every returned result is an object representing a row in the database. These objects can be modified and saved again to persistence:

```
<?php

// Manipulating a resultset of complete objects
foreach (Robots::find() as $robot) {
    $robot->year = 2000;
    $robot->save();
}
```

Sometimes records are obtained only to be presented to a user in read-only mode, in these cases it may be useful to change the way in which records are represented to facilitate their handling. The strategy used to represent objects returned in a resultset is called ‘hydration mode’:

```
<?php

use Phalcon\Mvc\Model\Resultset;

$robots = Robots::find();

//Return every robot as an array
$robots->setHydrateMode(Resultset::HYDRATE_ARRAYS);

foreach ($robots as $robot) {
    echo $robot['year'], PHP_EOL;
}

//Return every robot as an stdClass
$robots->setHydrateMode(Resultset::HYDRATE_OBJECTS);

foreach ($robots as $robot) {
    echo $robot->year, PHP_EOL;
}

//Return every robot as a Robots instance
$robots->setHydrateMode(Resultset::HYDRATE_RECORDS);

foreach ($robots as $robot) {
    echo $robot->year, PHP_EOL;
}
```

Hydration mode can also be passed as a parameter of ‘find’:

```
<?php

use Phalcon\Mvc\Model\Resultset;

$robots = Robots::find(array(
    'hydration' => Resultset::HYDRATE_ARRAYS
));

foreach ($robots as $robot) {
    echo $robot['year'], PHP_EOL;
}
```

2.13.9 Creating Updating/Records

The method `Phalcon\Mvc\Model::save()` allows you to create/update records according to whether they already exist in the table associated with a model. The save method is called internally by the create and update methods of `Phalcon\Mvc\Model`. For this to work as expected it is necessary to have properly defined a primary key in the entity to determine whether a record should be updated or created.

Also the method executes associated validators, virtual foreign keys and events that are defined in the model:

```
<?php

$robot      = new Robots();
$robot->type = "mechanical";
$robot->name = "Astro Boy";
$robot->year = 1952;
if ($robot->save() == false) {
    echo "Umh, We can't store robots right now: \n";
    foreach ($robot->getMessages() as $message) {
        echo $message, "\n";
    }
} else {
    echo "Great, a new robot was saved successfully!";
}
```

An array could be passed to “`save`” to avoid assign every column manually. `Phalcon\Mvc\Model` will check if there are setters implemented for the columns passed in the array giving priority to them instead of assign directly the values of the attributes:

```
<?php

$robot = new Robots();
$robot->save(array(
    "type" => "mechanical",
    "name" => "Astro Boy",
    "year" => 1952
));
```

Values assigned directly or via the array of attributes are escaped/sanitized according to the related attribute data type. So you can pass an insecure array without worrying about possible SQL injections:

```
<?php

$robot = new Robots();
$robot->save($_POST);
```

Without precautions mass assignment could allow attackers to set any database column’s value. Only use this feature if you want to permit a user to insert/update every column in the model, even if those fields are not in the submitted form.

You can set an additional parameter in ‘`save`’ to set a whitelist of fields that only must taken into account when doing the mass assignment:

```
<?php

$robot = new Robots();
$robot->save($_POST, array('name', 'type'));
```

Create/Update with Confidence

When an application has a lot of competition, we could be expecting create a record but it is actually updated. This could happen if we use Phalcon\\Mvc\\Model::save() to persist the records in the database. If we want to be absolutely sure that a record is created or updated, we can change the save() call with create() or update():

```
<?php

$robot      = new Robots();
$robot->type = "mechanical";
$robot->name = "Astro Boy";
$robot->year = 1952;

//This record only must be created
if ($robot->create() == false) {
    echo "Umh, We can't store robots right now: \n";
    foreach ($robot->getMessages() as $message) {
        echo $message, "\n";
    }
} else {
    echo "Great, a new robot was created successfully!";
}
```

These methods “create” and “update” also accept an array of values as parameter.

Auto-generated identity columns

Some models may have identity columns. These columns usually are the primary key of the mapped table. [Phalcon\\Mvc\\Model](#) can recognize the identity column omitting it in the generated SQL INSERT, so the database system can generate an auto-generated value for it. Always after creating a record, the identity field will be registered with the value generated in the database system for it:

```
<?php

$robot->save();

echo "The generated id is: ", $robot->id;
```

[Phalcon\\Mvc\\Model](#) is able to recognize the identity column. Depending on the database system, those columns may be serial columns like in PostgreSQL or auto_increment columns in the case of MySQL.

PostgreSQL uses sequences to generate auto-numeric values, by default, Phalcon tries to obtain the generated value from the sequence “table_field_seq”, for example: robots_id_seq, if that sequence has a different name, the method “getSequenceName” needs to be implemented:

```
<?php

use Phalcon\\Mvc\\Model;

class Robots extends Model
{

    public function getSequenceName()
    {
        return "robots_sequence_name";
    }
}
```

Storing related records

Magic properties can be used to store a records and its related properties:

```
<?php

// Create an artist
$artist      = new Artists();
$artist->name    = 'Shinichi Osawa';
$artist->country = 'Japan';

// Create an album
$album       = new Albums();
$album->name   = 'The One';
$album->artist  = $artist; //Assign the artist
$album->year   = 2008;

//Save both records
$album->save();
```

Saving a record and its related records in a has-many relation:

```
<?php

// Get an existing artist
$artist = Artists::findFirst('name = "Shinichi Osawa"');

// Create an album
$album      = new Albums();
$album->name    = 'The One';
$album->artist  = $artist;

$songs = array();

// Create a first song
$songs[0]      = new Songs();
$songs[0]->name    = 'Star Guitar';
$songs[0]->duration = '5:54';

// Create a second song
$songs[1]      = new Songs();
$songs[1]->name    = 'Last Days';
$songs[1]->duration = '4:29';

// Assign the songs array
$album->songs = $songs;

// Save the album + its songs
$album->save();
```

Saving the album and the artist at the same time implicitly makes use of a transaction so if anything goes wrong with saving the related records, the parent will not be saved either. Messages are passed back to the user for information regarding any errors.

Note: Adding related entities by overloading the following methods is not possible:

- PhalconMvcModel::beforeSave()
- PhalconMvcModel::beforeCreate()
- PhalconMvcModel::beforeUpdate()

You need to overload Phalcon\\Mvc\\Model::save() for this to work from within a model.

Validation Messages

Phalcon\\Mvc\\Model has a messaging subsystem that provides a flexible way to output or store the validation messages generated during the insert/update processes.

Each message consists of an instance of the class Phalcon\\Mvc\\Model\\Message. The set of messages generated can be retrieved with the method getMessages(). Each message provides extended information like the field name that generated the message or the message type:

```
<?php

if ($robot->save() == false) {
    foreach ($robot->getMessages() as $message) {
        echo "Message: ", $message->getMessage();
        echo "Field: ", $message->getField();
        echo "Type: ", $message->getType();
    }
}
```

Phalcon\\Mvc\\Model can generate the following types of validation messages:

Type	Description
PresenceOf	Generated when a field with a non-null attribute on the database is trying to insert/update a null value
ConstraintViolation	Generated when a field part of a virtual foreign key is trying to insert/update a value that doesn't exist in the referenced model
InvalidValue	Generated when a validator failed because of an invalid value
InvalidCreateAttempt	Produced when a record is attempted to be created but it already exists
InvalidUpdateAttempt	Produced when a record is attempted to be updated but it doesn't exist

The method getMessages() can be overridden in a model to replace/translate the default messages generated automatically by the ORM:

```
<?php

use Phalcon\\Mvc\\Model;

class Robots extends Model
{
    public function getMessages()
    {
        $messages = array();
        foreach (parent::getMessages() as $message) {
            switch ($message->getType()) {
                case 'InvalidCreateAttempt':
                    $messages[] = 'The record cannot be created because it already exists';
                    break;
                case 'InvalidUpdateAttempt':
                    $messages[] = 'The record cannot be updated because it already exists';
                    break;
                case 'PresenceOf':
                    $messages[] = 'The field ' . $message->getField() . ' is mandatory';
                    break;
            }
        }
    }
}
```

```

        }
        return $messages;
    }
}

```

Events and Events Manager

Models allow you to implement events that will be thrown when performing an insert/update/delete. They help define business rules for a certain model. The following are the events supported by `Phalcon\Mvc\Model` and their order of execution:

Operation	Name	Can stop operation?	Explanation
Inserting/Updating	beforeValidation	YES	Is executed before the fields are validated for not nulls/empty strings or foreign keys
Inserting	beforeValidationOnCreate	YES	Is executed before the fields are validated for not nulls/empty strings or foreign keys when an insertion operation is being made
Updating	beforeValidationOnUpdate	YES	Is executed before the fields are validated for not nulls/empty strings or foreign keys when an updating operation is being made
Inserting/Updating	onValidationFails	YES (already stopped)	Is executed after an integrity validator fails
Inserting	afterValidationOnCreate	YES	Is executed after the fields are validated for not nulls/empty strings or foreign keys when an insertion operation is being made
Updating	afterValidationOnUpdate	YES	Is executed after the fields are validated for not nulls/empty strings or foreign keys when an updating operation is being made
Inserting/Updating	afterValidation	YES	Is executed after the fields are validated for not nulls/empty strings or foreign keys
Inserting/Updating	beforeSave	YES	Runs before the required operation over the database system
Updating	beforeUpdate	YES	Runs before the required operation over the database system only when an updating operation is being made
Inserting	beforeCreate	YES	Runs before the required operation over the database system only when an inserting operation is being made
Updating	afterUpdate	NO	Runs after the required operation over the database system only when an updating operation is being made
Inserting	afterCreate	NO	Runs after the required operation over the database system only when an inserting operation is being made
Inserting/Updating	afterSave	NO	Runs after the required operation over the database system

Implementing Events in the Model's class

The easier way to make a model react to events is implement a method with the same name of the event in the model's class:

```

<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

```

```
public function beforeValidationOnCreate()
{
    echo "This is executed before creating a Robot!";
}
```

Events can be useful to assign values before performing an operation, for example:

```
<?php

use Phalcon\Mvc\Model;

class Products extends Model
{

    public function beforeCreate()
    {
        //Set the creation date
        $this->created_at = date('Y-m-d H:i:s');
    }

    public function beforeUpdate()
    {
        //Set the modification date
        $this->modified_in = date('Y-m-d H:i:s');
    }
}
```

Using a custom Events Manager

Additionally, this component is integrated with `Phalcon\Events\Manager`, this means we can create listeners that run when an event is triggered.

```
<?php

use Phalcon\Mvc\Model;
use Phalcon\Events\Manager as EventsManager;

class Robots extends Model
{

    public function initialize()
    {

        $eventsManager = new EventsManager();

        //Attach an anonymous function as a listener for "model" events
        $eventsManager->attach('model', function($event, $robot) {
            if ($event->getType() == 'beforeSave') {
                if ($robot->name == 'Scooby Doo') {
                    echo "Scooby Doo isn't a robot!";
                    return false;
                }
            }
            return true;
        });
    }
}
```

```
//Attach the events manager to the event
$this->setEventManager($eventsManager);
}

}
```

In the example given above, EventsManager only acts as a bridge between an object and a listener (the anonymous function). Events will be fired to the listener when ‘robots’ are saved:

```
<?php

$robot      = new Robots();
$robot->name = 'Scooby Doo';
$robot->year = 1969;
$robot->save();
```

If we want all objects created in our application use the same EventsManager, then we need to assign it to the Models Manager:

```
<?php

//Registering the modelsManager service
$di->setShared('modelsManager', function() {

    $eventsManager = new \Phalcon\Events\Manager();

    //Attach an anonymous function as a listener for "model" events
    $eventsManager->attach('model', function($event, $model) {

        //Catch events produced by the Robots model
        if (get_class($model) == 'Robots') {

            if ($event->getType() == 'beforeSave') {
                if ($model->name == 'Scooby Doo') {
                    echo "Scooby Doo isn't a robot!";
                    return false;
                }
            }
            return true;
        });
    });

    //Setting a default EventsManager
    $modelsManager = new ModelsManager();
    $modelsManager->setEventManager($eventsManager);
    return $modelsManager;
});
```

If a listener returns false that will stop the operation that is executing currently.

Implementing a Business Rule

When an insert, update or delete is executed, the model verifies if there are any methods with the names of the events listed in the table above.

We recommend that validation methods are declared protected to prevent that business logic implementation from being exposed publicly.

The following example implements an event that validates the year cannot be smaller than 0 on update or insert:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public function beforeSave()
    {
        if ($this->year < 0) {
            echo "Year cannot be smaller than zero!";
            return false;
        }
    }
}
```

Some events return false as an indication to stop the current operation. If an event doesn't return anything, `Phalcon\Mvc\Model` will assume a true value.

Validating Data Integrity

`Phalcon\Mvc\Model` provides several events to validate data and implement business rules. The special “validation” event allows us to call built-in validators over the record. Phalcon exposes a few built-in validators that can be used at this stage of validation.

The following example shows how to use it:

```
<?php

use Phalcon\Mvc\Model;
use Phalcon\Mvc\Model\Validator\Uniqueness;
use Phalcon\Mvc\Model\Validator\InclusionIn;

class Robots extends Model
{

    public function validation()
    {

        $this->validate(new InclusionIn(
            array(
                "field" => "type",
                "domain" => array("Mechanical", "Virtual")
            )
        ));

        $this->validate(new Uniqueness(
            array(
                "field" => "name",
                "message" => "The robot name must be unique"
            )
        ));

        return $this->validationHasFailed() != true;
    }
}
```

The above example performs a validation using the built-in validator “InclusionIn”. It checks the value of the field “type” in a domain list. If the value is not included in the method then the validator will fail and return false. The following built-in validators are available:

Name	Explanation	Example
PresenceOf	Validates that a field's value isn't null or empty string. This validator is automatically added based on the attributes marked as not null on the mapped table	Example
Email	Validates that field contains a valid email format	Example
ExclusionIn	Validates that a value is not within a list of possible values	Example
InclusionIn	Validates that a value is within a list of possible values	Example
Numericality	Validates that a field has a numeric format	Example
Regex	Validates that the value of a field matches a regular expression	Example
Uniqueness	Validates that a field or a combination of a set of fields are not present more than once in the existing records of the related table	Example
StringLength	Validates the length of a string	Example
Url	Validates that a value has a valid URL format	Example

In addition to the built-in validators, you can create your own validators:

```
<?php

use Phalcon\Mvc\Model\Validator;
use Phalcon\Mvc\Model\ValidatorInterface;

class MaxMinValidator extends Validator implements ValidatorInterface
{

    public function validate($model)
    {
        $field = $this->getOption('field');

        $min = $this->getOption('min');
        $max = $this->getOption('max');

        $value = $model->$field;

        if ($min <= $value && $value <= $max) {
            $this->appendMessage(

```

```

        "The field doesn't have the right range of values",
        $field,
        "MaxMinValidator"
    );
    return false;
}
return true;
}
}

```

Adding the validator to a model:

```

<?php

use Phalcon\Mvc\Model;

class Customers extends Model
{

    public function validation()
    {
        $this->validate(new MaxMinValidator(
            array(
                "field" => "price",
                "min"   => 10,
                "max"   => 100
            )
        ));
        if ($this->validationHasFailed() == true) {
            return false;
        }
    }
}

```

The idea of creating validators is make them reusable between several models. A validator can also be as simple as:

```

<?php

use Phalcon\Mvc\Model;
use Phalcon\Mvc\Model\Message;

class Robots extends Model
{

    public function validation()
    {
        if ($this->type == "Old") {
            $message = new Message(
                "Sorry, old robots are not allowed anymore",
                "type",
                "MyType"
            );
            $this->appendMessage($message);
            return false;
        }
        return true;
    }
}

```

Avoiding SQL injections

Every value assigned to a model attribute is escaped depending of its data type. A developer doesn't need to escape manually each value before storing it on the database. Phalcon uses internally the `bound parameters` capability provided by PDO to automatically escape every value to be stored in the database.

```
mysql> desc products;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| id | int(10) unsigned | NO | PRI | NULL | auto_increment |
| product_types_id | int(10) unsigned | NO | MUL | NULL | |
| name | varchar(70) | NO | | NULL | |
| price | decimal(16,2) | NO | | NULL | |
| active | char(1) | YES | | NULL | |
+-----+-----+-----+-----+-----+
5 rows in set (0.00 sec)
```

If we use just PDO to store a record in a secure way, we need to write the following code:

```
<?php

$name      = 'Artichoke';
$price     = 10.5;
$active    = 'Y';
$productTypeId = 1;

$sql = 'INSERT INTO products VALUES (null, :productTypeId, :name, :price, :active)';
$stmt = $db->prepare($sql);

$stmt->bindParam(':productTypeId', $productTypeId, PDO::PARAM_INT);
$stmt->bindParam(':name', $name, PDO::PARAM_STR, 70);
$stmt->bindParam(':price', doubleval($price));
$stmt->bindParam(':active', $active, PDO::PARAM_STR, 1);

$stmt->execute();
```

The good news is that Phalcon do this for you automatically:

```
<?php

$product          = new Products();
$product->product_types_id = 1;
$product->name    = 'Artichoke';
$product->price   = 10.5;
$product->active  = 'Y';
$product->create();
```

2.13.10 Skipping Columns

To tell Phalcon\ Mvc\ Model that always omits some fields in the creation and/or update of records in order to delegate the database system the assignation of the values by a trigger or a default:

```
<?php

use Phalcon\ Mvc\ Model;

class Robots extends Model
```

```
{
    public function initialize()
    {
        //Skips fields/columns on both INSERT/UPDATE operations
        $this->skipAttributes(array('year', 'price'));

        //Skips only when inserting
        $this->skipAttributesOnCreate(array('created_at'));

        //Skips only when updating
        $this->skipAttributesOnUpdate(array('modified_in'));
    }
}
```

This will ignore globally these fields on each INSERT/UPDATE operation on the whole application. If you want to ignore different attributes on different INSERT/UPDATE operations, you can specify the second parameter (boolean) - true for replacement. Forcing a default value can be done in the following way:

```
<?php

use Phalcon\Db\RawValue;

$robot           = new Robots();
$robot->name     = 'Bender';
$robot->year      = 1999;
$robot->created_at = new RawValue('default');
$robot->create();
```

A callback also can be used to create a conditional assignment of automatic default values:

```
<?php

use Phalcon\Mvc\Model;
use Phalcon\Db\RawValue;

class Robots extends Model
{
    public function beforeCreate()
    {
        if ($this->price > 10000) {
            $this->type = new RawValue('default');
        }
    }
}
```

Never use a \Phalcon\Db\RawValue to assign external data (such as user input) or variable data. The value of these fields is ignored when binding parameters to the query. So it could be used to attack the application injecting SQL.

Dynamic Update

SQL UPDATE statements are by default created with every column defined in the model (full all-field SQL update). You can change specific models to make dynamic updates, in this case, just the fields that had changed are used to create the final SQL statement.

In some cases this could improve the performance by reducing the traffic between the application and the database server, this specially helps when the table has blob/text fields:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{
    public function initialize()
    {
        $this->useDynamicUpdate(true);
    }
}
```

2.13.11 Deleting Records

The method `Phalcon\Mvc\Model::delete()` allows to delete a record. You can use it as follows:

```
<?php

$robot = Robots::findFirst(11);
if ($robot != false) {
    if ($robot->delete() == false) {
        echo "Sorry, we can't delete the robot right now: \n";
        foreach ($robot->getMessages() as $message) {
            echo $message, "\n";
        }
    } else {
        echo "The robot was deleted successfully!";
    }
}
```

You can also delete many records by traversing a resultset with a `foreach`:

```
<?php

foreach (Robots::find("type='mechanical'") as $robot) {
    if ($robot->delete() == false) {
        echo "Sorry, we can't delete the robot right now: \n";
        foreach ($robot->getMessages() as $message) {
            echo $message, "\n";
        }
    } else {
        echo "The robot was deleted successfully!";
    }
}
```

The following events are available to define custom business rules that can be executed when a delete operation is performed:

Operation	Name	Can stop operation?	Explanation
Deleting	beforeDelete	YES	Runs before the delete operation is made
Deleting	afterDelete	NO	Runs after the delete operation was made

With the above events can also define business rules in the models:

```
<?php

use Phalcon\Mvc\Model;
```

```

class Robots extends Model
{
    public function beforeDelete()
    {
        if ($this->status == 'A') {
            echo "The robot is active, it can't be deleted";
            return false;
        }
        return true;
    }
}

```

2.13.12 Validation Failed Events

Another type of events are available when the data validation process finds any inconsistency:

Operation	Name	Explanation
Insert or Update	notSave	Triggered when the INSERT or UPDATE operation fails for any reason
Insert, Delete or Update	onValidation-Fails	Triggered when any data manipulation operation fails

2.13.13 Behaviors

Behaviors are shared conducts that several models may adopt in order to re-use code, the ORM provides an API to implement behaviors in your models. Also, you can use the events and callbacks as seen before as an alternative to implement Behaviors with more freedom.

A behavior must be added in the model initializer, a model can have zero or more behaviors:

```

<?php

use Phalcon\Mvc\Model;
use Phalcon\Mvc\Model\Behavior\Timestampable;

class Users extends Model
{
    public $id;

    public $name;

    public $created_at;

    public function initialize()
    {
        $this->addBehavior(new Timestampable(
            array(
                'beforeCreate' => array(
                    'field'      => 'created_at',
                    'format'     => 'Y-m-d'
                )
            )
        ));
    }
}

```

The following built-in behaviors are provided by the framework:

Name	Description
Timestampable	Allows to automatically update a model's attribute saving the datetime when a record is created or updated
SoftDelete	Instead of permanently delete a record it marks the record as deleted changing the value of a flag column

Timestampable

This behavior receives an array of options, the first level key must be an event name indicating when the column must be assigned:

```
<?php

use Phalcon\Mvc\Model\Behavior\Timestampable;

public function initialize()
{
    $this->addBehavior(new Timestampable(
        array(
            'beforeCreate' => array(
                'field'      => 'created_at',
                'format'     => 'Y-m-d'
            )
        )
    ));
}
```

Each event can have its own options, ‘field’ is the name of the column that must be updated, if ‘format’ is a string it will be used as format of the PHP’s function `date`, format can also be an anonymous function providing you the free to generate any kind timestamp:

```
<?php

use Phalcon\Mvc\Model\Behavior\Timestampable;

public function initialize()
{
    $this->addBehavior(new Timestampable(
        array(
            'beforeCreate' => array(
                'field'      => 'created_at',
                'format'     => function() {
                    $datetime = new \DateTimeZone('Europe/Stockholm'));
                    return $datetime->format('Y-m-d H:i:sP');
                }
            )
        )
    ));
}
```

If the option ‘format’ is omitted a timestamp using the PHP’s function `time`, will be used.

SoftDelete

This behavior can be used in the following way:

```
<?php

use Phalcon\Mvc\Model;
use Phalcon\Mvc\Model\Behavior\SoftDelete;

class Users extends Model
{

    const DELETED = 'D';

    const NOT_DELETED = 'N';

    public $id;

    public $name;

    public $status;

    public function initialize()
    {
        $this->addBehavior(new SoftDelete(
            array(
                'field' => 'status',
                'value' => Users::DELETED
            )
        ));
    }
}
```

This behavior accepts two options: ‘field’ and ‘value’, ‘field’ determines what field must be updated and ‘value’ the value to be deleted. Let’s pretend the table ‘users’ has the following data:

```
mysql> select * from users;
+----+-----+-----+
| id | name | status |
+----+-----+-----+
| 1 | Lana | N |
| 2 | Brandon | N |
+----+-----+-----+
2 rows in set (0.00 sec)
```

If we delete any of the two records the status will be updated instead of delete the record:

```
<?php

Users::findFirst(2)->delete();
```

The operation will result in the following data in the table:

```
mysql> select * from users;
+----+-----+-----+
| id | name | status |
+----+-----+-----+
| 1 | Lana | N |
| 2 | Brandon | D |
+----+-----+-----+
2 rows in set (0.01 sec)
```

Note that you need to specify the deleted condition in your queries to effectively ignore them as deleted records, this

behavior doesn't support that.

Creating your own behaviors

The ORM provides an API to create your own behaviors. A behavior must be a class implementing the `Phalcon\Mvc\Model\BehaviorInterface`. Also, `Phalcon\Mvc\Model\Behavior` provides most of the methods needed to ease the implementation of behaviors.

The following behavior is an example, it implements the Blamable behavior which helps identify the user that is performed operations over a model:

```
<?php

use Phalcon\Mvc\Model\Behavior;
use Phalcon\Mvc\Model\BehaviorInterface;

class Blamable extends Behavior implements BehaviorInterface
{

    public function notify($eventType, $model)
    {
        switch ($eventType) {

            case 'afterCreate':
            case 'afterDelete':
            case 'afterUpdate':

                $userName = // ... get the current user from session

                //Store in a log the username - event type and primary key
                file_put_contents(
                    'logs/blamable-log.txt',
                    $userName . ' ' . $eventType . ' ' . $model->id
                );
                break;

            default:
                /* ignore the rest of events */
        }
    }
}
```

The former is a very simple behavior, but it illustrates how to create a behavior, now let's add this behavior to a model:

```
<?php

use Phalcon\Mvc\Model;

class Profiles extends Model
{

    public function initialize()
    {
        $this->addBehavior(new Blamable());
    }
}
```

A behavior is also capable of intercepting missing methods on your models:

```
<?php

use Phalcon\Tag;
use Phalcon\Mvc\Model\Behavior;
use Phalcon\Mvc\Model\BehaviorInterface;

class Sluggable extends Behavior implements BehaviorInterface
{

    public function missingMethod($model, $method, $arguments=array())
    {
        // if the method is 'getSlug' convert the title
        if ($method == 'getSlug') {
            return Tag::friendlyTitle($model->title);
        }
    }
}
```

Call that method on a model that implements Sluggable returns a SEO friendly title:

```
<?php

$title = $post->getSlug();
```

Using Traits as behaviors

Starting from PHP 5.4 you can use [Traits](#) to re-use code in your classes, this is another way to implement custom behaviors. The following trait implements a simple version of the Timestampable behavior:

```
<?php

trait MyTimestampable
{

    public function beforeCreate()
    {
        $this->created_at = date('r');
    }

    public function beforeUpdate()
    {
        $this->updated_at = date('r');
    }
}
```

Then you can use it in your model as follows:

```
<?php

use Phalcon\Mvc\Model;

class Products extends Model
{
    use MyTimestampable;
}
```

2.13.14 Transactions

When a process performs multiple database operations, it is often that each step is completed successfully so that data integrity can be maintained. Transactions offer the ability to ensure that all database operations have been executed successfully before the data are committed to the database.

Transactions in Phalcon allow you to commit all operations if they have been executed successfully or rollback all operations if something went wrong.

Manual Transactions

If an application only uses one connection and the transactions aren't very complex, a transaction can be created by just moving the current connection to transaction mode, doing a rollback or commit if the operation is successfully or not:

```
<?php

use Phalcon\Mvc\Controller;

class RobotsController extends Controller
{
    public function saveAction()
    {
        $this->db->begin();

        $robot           = new Robots();
        $robot->name     = "WALL·E";
        $robot->created_at = date("Y-m-d");

        if ($robot->save() == false) {
            $this->db->rollback();
            return;
        }

        $robotPart       = new RobotParts();
        $robotPart->robots_id = $robot->id;
        $robotPart->type      = "head";

        if ($robotPart->save() == false) {
            $this->db->rollback();
            return;
        }

        $this->db->commit();
    }
}
```

Implicit Transactions

Existing relationships can be used to store records and their related instances, this kind of operation implicitly creates a transaction to ensure that data are correctly stored:

```
<?php

$robotPart       = new RobotParts();
$robotPart->type      = "head";
```

```
$robot           = new Robots();
$robot->name    = "WALL·E";
$robot->created_at = date("Y-m-d");
$robot->robotPart = $robotPart;

$robot->save(); //Creates an implicit transaction to store both records
```

Isolated Transactions

Isolated transactions are executed in a new connection ensuring that all the generated SQL, virtual foreign key checks and business rules are isolated from the main connection. This kind of transaction requires a transaction manager that globally manages each transaction created ensuring that they are correctly rolled back/committed before ending the request:

```
<?php

use Phalcon\Mvc\Model\Transaction\Failed as TxFailed;
use Phalcon\Mvc\Model\Transaction\Manager as TxManager;

try {

    //Create a transaction manager
    $manager      = new TxManager();

    // Request a transaction
    $transaction = $manager->get();

    $robot           = new Robots();
    $robot->setTransaction($transaction);
    $robot->name    = "WALL·E";
    $robot->created_at = date("Y-m-d");
    if ($robot->save() == false) {
        $transaction->rollback("Cannot save robot");
    }

    $robotPart       = new RobotParts();
    $robotPart->setTransaction($transaction);
    $robotPart->robots_id   = $robot->id;
    $robotPart->type       = "head";
    if ($robotPart->save() == false) {
        $transaction->rollback("Cannot save robot part");
    }

    //Everything goes fine, let's commit the transaction
    $transaction->commit();
}

} catch(TxFailed $e) {
    echo "Failed, reason: ", $e->getMessage();
}
```

Transactions can be used to delete many records in a consistent way:

```
<?php

use Phalcon\Mvc\Model\Transaction\Failed as TxFailed;
use Phalcon\Mvc\Model\Transaction\Manager as TxManager;
```

```

try {

    //Create a transaction manager
    $manager      = new TxManager();

    //Request a transaction
    $transaction = $manager->get();

    //Get the robots will be deleted
    foreach (Robots::find("type = 'mechanical'") as $robot) {
        $robot->setTransaction($transaction);
        if ($robot->delete() == false) {
            //Something goes wrong, we should to rollback the transaction
            foreach ($robot->getMessages() as $message) {
                $transaction->rollback($message->getMessage());
            }
        }
    }

    //Everything goes fine, let's commit the transaction
    $transaction->commit();

    echo "Robots were deleted successfully!";

} catch(TxFailed $e) {
    echo "Failed, reason: ", $e->getMessage();
}

```

Transactions are reused no matter where the transaction object is retrieved. A new transaction is generated only when a commit() or rollback() is performed. You can use the service container to create the global transaction manager for the entire application:

```

<?php

use Phalcon\Mvc\Model\Transaction\Manager as TransactionManager

$di->setShared('transactions', function() {
    return new TransactionManager();
});

```

Then access it from a controller or view:

```

<?php

use Phalcon\Mvc\Controller;

class ProductsController extends Controller
{

    public function saveAction()
    {

        //Obtain the TransactionsManager from the services container
        $manager      = $this->di->getTransactions();

        //Or
        $manager      = $this->transactions;

        //Request a transaction
    }
}

```

```

    $transaction = $manager->get();

    //...
}

}

```

While a transaction is active, the transaction manager will always return the same transaction across the application.

2.13.15 Independent Column Mapping

The ORM supports an independent column map, which allows the developer to use different column names in the model to the ones in the table. Phalcon will recognize the new column names and will rename them accordingly to match the respective columns in the database. This is a great feature when one needs to rename fields in the database without having to worry about all the queries in the code. A change in the column map in the model will take care of the rest. For example:

```

<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public $code;

    public $theName;

    public $theType;

    public $theYear;

    public function columnMap()
    {
        // Keys are the real names in the table and
        // the values their names in the application
        return array(
            'id'      => 'code',
            'the_name' => 'theName',
            'the_type' => 'theType',
            'the_year' => 'theYear'
        );
    }
}

```

Then you can use the new names naturally in your code:

```

<?php

// Find a robot by its name
$robot = Robots::findFirst("theName = 'Voltron'");
echo $robot->theName, "\n";

// Get robots ordered by type
$robot = Robots::find(array('order' => 'theType DESC'));
foreach ($robots as $robot) {
    echo 'Code: ', $robot->code, "\n";
}

```

```
// Create a robot
$robot      = new Robots();
$robot->code    = '10101';
$robot->theName = 'Bender';
$robot->theType = 'Industrial';
$robot->theYear = 2999;
$robot->save();
```

Take into consideration the following the next when renaming your columns:

- References to attributes in relationships/validators must use the new names
- Refer the real column names will result in an exception by the ORM

The independent column map allow you to:

- Write applications using your own conventions
- Eliminate vendor prefixes/suffixes in your code
- Change column names without change your application code

2.13.16 Operations over Resultsets

If a resultset is composed of complete objects, the resultset is in the ability to perform operations on the records obtained in a simple manner:

Updating related records

Instead of doing this:

```
<?php

foreach ($robots->getParts() as $part) {
    $part->stock      = 100;
    $part->updated_at = time();
    if ($part->update() == false) {
        foreach ($part->getMessages() as $message) {
            echo $message;
        }
        break;
}
```

you can do this:

```
<?php

$robots->getParts()->update(array(
    'stock' => 100,
    'updated_at' => time()
));
```

‘update’ also accepts an anonymous function to filter what records must be updated:

```
<?php

$data = array(
```

```

'stock'      => 100,
'updated_at' => time()
);

//Update all the parts except those whose type is basic
$robots->getParts()->update($data, function($part) {
    if ($part->type == Part::TYPE_BASIC) {
        return false;
    }
    return true;
});
```

Deleting related records

Instead of doing this:

```
<?php

foreach ($robots->getParts() as $part) {
    if ($part->delete() == false) {
        foreach ($part->getMessages() as $message) {
            echo $message;
        }
        break;
    }
}
```

you can do this:

```
<?php

$robots->getParts()->delete();
```

‘delete’ also accepts an anonymous function to filter what records must be deleted:

```
<?php

//Delete only whose stock is greater or equal than zero
$robots->getParts()->delete(function($part) {
    if ($part->stock < 0) {
        return false;
    }
    return true;
});
```

2.13.17 Record Snapshots

Specific models could be set to maintain a record snapshot when they’re queried. You can use this feature to implement auditing or just to know what fields are changed according to the data queried from the persistence:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{
```

```
public function initialize()
{
    $this->keepSnapshots(true);
}
```

When activating this feature the application consumes a bit more of memory to keep track of the original values obtained from the persistence. In models that have this feature activated you can check what fields changed:

```
<?php

//Get a record from the database
$robot = Robots::findFirst();

//Change a column
$robot->name = 'Other name';

var_dump($robot->getChangedFields()); // ['name']
var_dump($robot->hasChanged('name'));// true
var_dump($robot->hasChanged('type'));// false
```

2.13.18 Models Meta-Data

To speed up development `Phalcon\Mvc\Model` helps you to query fields and constraints from tables related to models. To achieve this, `Phalcon\Mvc\Model\MetaData` is available to manage and cache table meta-data.

Sometimes it is necessary to get those attributes when working with models. You can get a meta-data instance as follows:

```
<?php

$robot      = new Robots();

// Get Phalcon\Mvc\Model\MetaData instance
$metaData   = $robot->getModelsMetaData();

// Get robots fields names
$attributes = $metaData->getAttributes($robot);
print_r($attributes);

// Get robots fields data types
$dataTypes = $metaData->getDataTypes($robot);
print_r($dataTypes);
```

Caching Meta-Data

Once the application is in a production stage, it is not necessary to query the meta-data of the table from the database system each time you use the table. This could be done caching the meta-data using any of the following adapters:

Adapter	Description	API
Memory	This adapter is the default. The meta-data is cached only during the request. When the request is completed, the meta-data are released as part of the normal memory of the request. This adapter is perfect when the application is in development so as to refresh the meta-data in each request containing the new and/or modified fields.	Phalcon\Mvc\Model\MetaData\Memory
Session	This adapter stores meta-data in the <code>\$_SESSION</code> superglobal. This adapter is recommended only when the application is actually using a small number of models. The meta-data are refreshed every time a new session starts. This also requires the use of <code>session_start()</code> to start the session before using any models.	Phalcon\Mvc\Model\MetaData\Session
Apc	This adapter uses the Alternative PHP Cache (APC) to store the table meta-data. You can specify the lifetime of the meta-data with options. This is the most recommended way to store meta-data when the application is in production stage.	Phalcon\Mvc\Model\MetaData\Apc
XCache	This adapter uses XCache to store the table meta-data. You can specify the lifetime of the meta-data with options. This is the most recommended way to store meta-data when the application is in production stage.	Phalcon\Mvc\Model\MetaData\Xcache
Files	This adapter uses plain files to store meta-data. By using this adapter the disk-reading is increased but the database access is reduced	Phalcon\Mvc\Model\MetaData\Files

As other ORM's dependencies, the metadata manager is requested from the services container:

```
<?php

use Phalcon\Mvc\Model\MetaData\Apc as ApcMetaData;

$di['modelsMetadata'] = function() {

    // Create a meta-data manager with APC
    $metaData = new ApcMetaData(array(
        "lifetime" => 86400,
        "prefix"   => "my-prefix"
    ));

    return $metaData;
};
```

Meta-Data Strategies

As mentioned above the default strategy to obtain the model's meta-data is database introspection. In this strategy, the information schema is used to know the fields in a table, its primary key, nullable fields, data types, etc.

You can change the default meta-data introspection in the following way:

```
<?php

use Phalcon\Mvc\Model\MetaData\Apc as ApcMetaData;

$di['modelsMetadata'] = function() {

    // Instantiate a meta-data adapter
    $metaData = new ApcMetaData(array(
        "lifetime" => 86400,
        "prefix"   => "my-prefix"
    ));

    // Set a custom meta-data introspection strategy
    $metaData->setStrategy(new MyIntrospectionStrategy());
};
```

```
    return $metaData;
};
```

Database Introspection Strategy

This strategy doesn't require any customization and is implicitly used by all the meta-data adapters.

Annotations Strategy

This strategy makes use of [annotations](#) to describe the columns in a model:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    /**
     * @Primary
     * @Identity
     * @Column(type="integer", nullable=false)
     */
    public $id;

    /**
     * @Column(type="string", length=70, nullable=false)
     */
    public $name;

    /**
     * @Column(type="string", length=32, nullable=false)
     */
    public $type;

    /**
     * @Column(type="integer", nullable=false)
     */
    public $year;
}
```

Annotations must be placed in properties that are mapped to columns in the mapped source. Properties without the `@Column` annotation are handled as simple class attributes.

The following annotations are supported:

Name	Description
Primary	Mark the field as part of the table's primary key
Identity	The field is an auto_increment/serial column
Column	This marks an attribute as a mapped column

The annotation `@Column` supports the following parameters:

Name	Description
type	The column's type (string, integer, decimal, boolean)
length	The column's length if any
nullable	Set whether the column accepts null values or not

The annotations strategy could be set up this way:

```
<?php

use Phalcon\Mvc\Model\MetaData\Apc as ApcMetaData;
use Phalcon\Mvc\Model\MetaData\Strategy\Annotations as StrategyAnnotations;

$di['modelsMetadata'] = function() {

    // Instantiate a meta-data adapter
    $metaData = new ApcMetaData(array(
        "lifetime" => 86400,
        "prefix"   => "my-prefix"
    ));

    //Set a custom meta-data database introspection
    $metaData->setStrategy(new StrategyAnnotations());

    return $metaData;
};
```

Manual Meta-Data

Phalcon can obtain the metadata for each model automatically without the developer must set them manually using any of the introspection strategies presented above.

The developer also has the option of define the metadata manually. This strategy overrides any strategy set in the meta-data manager. New columns added/modified/removed to/from the mapped table must be added/modifed/removed also for everything to work properly.

The following example shows how to define the meta-data manually:

```
<?php

use Phalcon\Mvc\Model;
use Phalcon\Db\Column;
use Phalcon\Mvc\Model\MetaData;

class Robots extends Model
{

    public function metaData()
    {
        return array(

            // Every column in the mapped table
            MetaData::MODELS_ATTRIBUTES => array(
                'id', 'name', 'type', 'year'
            ),

            // Every column part of the primary key
            MetaData::MODELS_PRIMARY_KEY => array(
                'id'
            ),

            // Every column that isn't part of the primary key
            MetaData::MODELS_NON_PRIMARY_KEY => array(
                'name', 'type', 'year'
            )
        );
    }
}
```

```
) ,  
  
    // Every column that doesn't allow null values  
    MetaData::MODELS_NOT_NULL => array(  
        'id', 'name', 'type'  
    ) ,  
  
    // Every column and their data types  
    MetaData::MODELS_DATA_TYPES => array(  
        'id' => Column::TYPE_INTEGER,  
        'name' => Column::TYPE_VARCHAR,  
        'type' => Column::TYPE_VARCHAR,  
        'year' => Column::TYPE_INTEGER  
    ) ,  
  
    // The columns that have numeric data types  
    MetaData::MODELS_DATA_TYPES_NUMERIC => array(  
        'id' => true,  
        'year' => true,  
    ) ,  
  
    // The identity column, use boolean false if the model doesn't have  
    // an identity column  
    MetaData::MODELS_IDENTITY_COLUMN => 'id',  
  
    // How every column must be bound/casted  
    MetaData::MODELS_DATA_TYPES_BIND => array(  
        'id' => Column::BIND_PARAM_INT,  
        'name' => Column::BIND_PARAM_STR,  
        'type' => Column::BIND_PARAM_STR,  
        'year' => Column::BIND_PARAM_INT  
    ) ,  
  
    // Fields that must be ignored from INSERT SQL statements  
    MetaData::MODELS_AUTOMATIC_DEFAULT_INSERT => array(  
        'year' => true  
    ) ,  
  
    // Fields that must be ignored from UPDATE SQL statements  
    MetaData::MODELS_AUTOMATIC_DEFAULT_UPDATE => array(  
        'year' => true  
    ) ,  
  
    // Default values for columns  
    MetaData::MODELS_DEFAULT_VALUES => array(  
        'year' => '2015'  
    ) ,  
  
    // Fields that allow empty strings  
    MetaData::MODELS_EMPTY_STRING_VALUES => array(  
        'name' => true  
    )  
);  
}  
}
```

2.13.19 Pointing to a different schema

If a model is mapped to a table that is in a different schemas/databases than the default. You can use the `getSchema` method to define that:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public function getSchema()
    {
        return "toys";
    }
}
```

2.13.20 Setting multiple databases

In Phalcon, all models can belong to the same database connection or have an individual one. Actually, when `Phalcon\Mvc\Model` needs to connect to the database it requests the “db” service in the application’s services container. You can overwrite this service setting it in the initialize method:

```
<?php

use Phalcon\Db\Adapter\Pdo\Mysql as MysqlPdo;
use Phalcon\Db\Adapter\Pdo\PostgreSQL as PostgreSQPdo;

//This service returns a MySQL database
$di->set('dbMysql', function() {
    return new MysqlPdo(array(
        "host"      => "localhost",
        "username"  => "root",
        "password"  => "secret",
        "dbname"    => "invo"
    ));
});

//This service returns a PostgreSQL database
$di->set('dbPostgres', function() {
    return new PostgreSQPdo(array(
        "host"      => "localhost",
        "username"  => "postgres",
        "password"  => "",
        "dbname"    => "invo"
    ));
});
```

Then, in the Initialize method, we define the connection service for the model:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{
```

```
public function initialize()
{
    $this->setConnectionService('dbPostgres');
}
```

But Phalcon offers you more flexibility, you can define the connection that must be used to ‘read’ and for ‘write’. This is specially useful to balance the load to your databases implementing a master-slave architecture:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public function initialize()
    {
        $this->setReadConnectionService('dbSlave');
        $this->setWriteConnectionService('dbMaster');
    }
}
```

The ORM also provides Horizontal Sharding facilities, by allowing you to implement a ‘shard’ selection according to the current query conditions:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{
    /**
     * Dynamically selects a shard
     *
     * @param array $intermediate
     * @param array $bindParams
     * @param array $bindTypes
     */
    public function selectReadConnection($intermediate, $bindParams, $bindTypes)
    {
        //Check if there is a 'where' clause in the select
        if (isset($intermediate['where'])) {

            $conditions = $intermediate['where'];

            //Choose the possible shard according to the conditions
            if ($conditions['left']['name'] == 'id') {
                $id = $conditions['right']['value'];
                if ($id > 0 && $id < 10000) {
                    return $this->getDI()->get('dbShard1');
                }
                if ($id > 10000) {
                    return $this->getDI()->get('dbShard2');
                }
            }
        }
    }
}
```

```
//Use a default shard
    return $this->getDI()->get('dbShard0');
}
}
```

The method ‘selectReadConnection’ is called to choose the right connection, this method intercepts any new query executed:

```
<?php

$robot = Robots::findFirst('id = 101');
```

2.13.21 Logging Low-Level SQL Statements

When using high-level abstraction components such as `Phalcon\Mvc\Model` to access a database, it is difficult to understand which statements are finally sent to the database system. `Phalcon\Mvc\Model` is supported internally by `Phalcon\Db`. `Phalcon\Logger` interacts with `Phalcon\Db`, providing logging capabilities on the database abstraction layer, thus allowing us to log SQL statements as they happen.

```
<?php

use Phalcon\Logger;
use Phalcon\Events\Manager;
use Phalcon\Logger\Adapter\File as FileLogger;
use Phalcon\Db\Adapter\Pdo\Mysql as Connection;

$di->set('db', function() {

    $eventsManager = new EventsManager();

    $logger = new FileLogger("app/logs/debug.log");

    //Listen all the database events
    $eventsManager->attach('db', function($event, $connection) use ($logger) {
        if ($event->getType() == 'beforeQuery') {
            $logger->log($connection->getSQLStatement(), Logger::INFO);
        }
    });

    $connection = new Connection(array(
        "host"      => "localhost",
        "username"  => "root",
        "password"  => "secret",
        "dbname"    => "invo"
    ));

    //Assign the eventsManager to the db adapter instance
    $connection->setEventsManager($eventsManager);

    return $connection;
});
```

As models access the default database connection, all SQL statements that are sent to the database system will be logged in the file:

```
<?php
```

```
$robot           = new Robots();
$robot->name     = "Robby the Robot";
$robot->created_at = "1956-07-21";
if ($robot->save() == false) {
    echo "Cannot save robot";
}
```

As above, the file `app/logs/db.log` will contain something like this:

```
[Mon, 30 Apr 12 13:47:18 -0500] [DEBUG] [Resource Id #77] INSERT INTO robots
(name, created_at) VALUES ('Robby the Robot', '1956-07-21')
```

2.13.22 Profiling SQL Statements

Thanks to Phalcon\Db, the underlying component of Phalcon\Mvc\Model, it's possible to profile the SQL statements generated by the ORM in order to analyze the performance of database operations. With this you can diagnose performance problems and to discover bottlenecks.

```
<?php

use Phalcon\Db\Profiler as ProfilerDb;
use Phalcon\Events\Manager as ManagerEvent;
use Phalcon\Db\Adapter\Pdo\Mysql as MysqlPdo;

$di->set('profiler', function() {
    return new ProfilerDb();
}, true);

$di->set('db', function() use ($di) {

    $eventsManager = new ManagerEvent();

    //Get a shared instance of the DbProfiler
    $profiler      = $di->getProfiler();

    //Listen all the database events
    $eventsManager->attach('db', function($event, $connection) use ($profiler) {
        if ($event->getType() == 'beforeQuery') {
            $profiler->startProfile($connection->getSQLStatement());
        }
        if ($event->getType() == 'afterQuery') {
            $profiler->stopProfile();
        }
    });

    $connection = new MysqlPdo(array(
        "host"      => "localhost",
        "username"  => "root",
        "password"  => "secret",
        "dbname"    => "invo"
    ));

    //Assign the eventsManager to the db adapter instance
    $connection->setEventsManager($eventsManager);

    return $connection;
});
```

Profiling some queries:

```
<?php

// Send some SQL statements to the database
Robots:::find();
Robots:::find(array("order" => "name"));
Robots:::find(array("limit" => 30));

//Get the generated profiles from the profiler
$profiles = $di->get('profiler')->getProfiles();

foreach ($profiles as $profile) {
    echo "SQL Statement: ", $profile->getSQLStatement(), "\n";
    echo "Start Time: ", $profile->getInitialTime(), "\n";
    echo "Final Time: ", $profile->getFinalTime(), "\n";
    echo "Total Elapsed Time: ", $profile->getTotalElapsedSeconds(), "\n";
}
```

Each generated profile contains the duration in milliseconds that each instruction takes to complete as well as the generated SQL statement.

2.13.23 Injecting services into Models

You may be required to access the application services within a model, the following example explains how to do that:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public function notSave()
    {
        //Obtain the flash service from the DI container
        $flash = $this->getDI()->getFlash();

        //Show validation messages
        foreach ($this->getMessages() as $message) {
            $flash->error($message);
        }
    }
}
```

The “notSave” event is triggered every time that a “create” or “update” action fails. So we’re flashing the validation messages obtaining the “flash” service from the DI container. By doing this, we don’t have to print messages after each save.

2.13.24 Disabling/Enabling Features

In the ORM we have implemented a mechanism that allow you to enable/disable specific features or options globally on the fly. According to how you use the ORM you can disable that you aren’t using. These options can also be temporarily disabled if required:

```
<?php

use Phalcon\Mvc\Model;

Model::setup(array(
    'events' => false,
    'columnRenaming' => false
));

```

The available options are:

Option	Description	De-fault
events	Enables/Disables callbacks, hooks and event notifications from all the models	true
columnRenaming	Enables/Disables the column renaming	true
notNullValidations	The ORM automatically validate the not null columns present in the mapped table	true
virtualForeignKeys	Enables/Disables the virtual foreign keys	true
phqlLiterals	Enables/Disables literals in the PHQL parser	true
lateStateBinding	Enables/Disables late state binding of the method MvcModel::cloneResultMap	false

2.13.25 Stand-Alone component

Using `Phalcon\Mvc\Model` in a stand-alone mode can be demonstrated below:

```
<?php

use Phalcon\DI;
use Phalcon\Mvc\Model;
use Phalcon\Mvc\Model\Manager as ModelsManager;
use Phalcon\Db\Adapter\Pdo\Sqlite as Connection;
use Phalcon\Mvc\Model\MetaData\Memory as MetaData;

$di = new DI();

//Setup a connection
$di->set('db', new Connection(array(
    "dbname" => "sample.db"
)));

//Set a models manager
$di->set('modelsManager', new ModelsManager());

//Use the memory meta-data adapter or other
$di->set('modelsMetadata', new MetaData());

//Create a model
class Robots extends Model
{

}

//Use the model
echo Robots::count();
```

2.14 Phalcon Query Language (PHQL)

Phalcon Query Language, PhalconQL or simply PHQL is a high-level, object-oriented SQL dialect that allows to write queries using a standardized SQL-like language. PHQL is implemented as a parser (written in C) that translates syntax in that of the target RDBMS.

To achieve the highest performance possible, Phalcon provides a parser that uses the same technology as [SQLite](#). This technology provides a small in-memory parser with a very low memory footprint that is also thread-safe.

The parser first checks the syntax of the pass PHQL statement, then builds an intermediate representation of the statement and finally it converts it to the respective SQL dialect of the target RDBMS.

In PHQL, we've implemented a set of features to make your access to databases more secure:

- Bound parameters are part of the PHQL language helping you to secure your code
- PHQL only allows one SQL statement to be executed per call preventing injections
- PHQL ignores all SQL comments which are often used in SQL injections
- PHQL only allows data manipulation statements, avoiding altering or dropping tables/databases by mistake or externally without authorization
- PHQL implements a high-level abstraction allowing you to handle tables as models and fields as class attributes

2.14.1 Usage Example

To better explain how PHQL works consider the following example. We have two models “Cars” and “Brands”:

```
<?php

use Phalcon\Mvc\Model;

class Cars extends Model
{
    public $id;
    public $name;
    public $brand_id;
    public $price;
    public $year;
    public $style;

    /**
     * This model is mapped to the table sample_cars
     */
    public function getSource()
    {
        return 'sample_cars';
    }

    /**
     * A car only has a Brand, but a Brand have many Cars
     */
    public function initialize()
```

```
{
    $this->belongsTo('brand_id', 'Brands', 'id');
}
}
```

And every Car has a Brand, so a Brand has many Cars:

```
<?php

use Phalcon\Mvc\Model;

class Brands extends Model
{

    public $id;

    public $name;

    /**
     * The model Brands is mapped to the "sample_brands" table
     */
    public function getSource()
    {
        return 'sample_brands';
    }

    /**
     * A Brand can have many Cars
     */
    public function initialize()
    {
        $this->hasMany('id', 'Cars', 'brand_id');
    }
}
```

2.14.2 Creating PHQL Queries

PHQL queries can be created just by instantiating the class `Phalcon\Mvc\Model\Query`:

```
<?php

use Phalcon\Mvc\Model\Query;

// Instantiate the Query
$query = new Query("SELECT * FROM Cars", $this->getDI());

// Execute the query returning a result if any
$cars = $query->execute();
```

From a controller or a view, it's easy to create/execute them using an injected models manager:

```
<?php

// Executing a simple query
$query = $this->modelsManager->createQuery("SELECT * FROM Cars");
$cars = $query->execute();

// With bound parameters
```

```
$query = $this->modelsManager->createQuery("SELECT * FROM Cars WHERE name = :name:");
$cars = $query->execute(array(
    'name' => 'Audi'
));
```

Or simply execute it:

```
<?php

// Executing a simple query
$cars = $this->modelsManager->executeQuery("SELECT * FROM Cars");

// Executing with bound parameters
$cars = $this->modelsManager->executeQuery("SELECT * FROM Cars WHERE name = :name:", array(
    'name' => 'Audi'
));
```

2.14.3 Selecting Records

As the familiar SQL, PHQL allows querying of records using the SELECT statement we know, except that instead of specifying tables, we use the models classes:

```
<?php

$query = $manager->createQuery("SELECT * FROM Cars ORDER BY Cars.name");
$query = $manager->createQuery("SELECT Cars.name FROM Cars ORDER BY Cars.name");
```

Classes in namespaces are also allowed:

```
<?php

$phql = "SELECT * FROM Formula\Cars ORDER BY Formula\Cars.name";
$query = $manager->createQuery($phql);

$phql = "SELECT Formula\Cars.name FROM Formula\Cars ORDER BY Formula\Cars.name";
$query = $manager->createQuery($phql);

$phql = "SELECT c.name FROM Formula\Cars c ORDER BY c.name";
$query = $manager->createQuery($phql);
```

Most of the SQL standard is supported by PHQL, even nonstandard directives such as LIMIT:

```
<?php

$phql = "SELECT c.name FROM Cars AS c "
. "WHERE c.brand_id = 21 ORDER BY c.name LIMIT 100";
$query = $manager->createQuery($phql);
```

Result Types

Depending on the type of columns we query, the result type will vary. If you retrieve a single whole object, then the object returned is a [Phalcon\Mvc\Model\Resultset\Simple](#). This kind of resultset is a set of complete model objects:

```
<?php

$phql = "SELECT c.* FROM Cars AS c ORDER BY c.name";
```

```
$cars = $manager->executeQuery($phql);
foreach ($cars as $car) {
    echo "Name: ", $car->name, "\n";
}
```

This is exactly the same as:

```
<?php

$cars = Cars::find(array("order" => "name"));
foreach ($cars as $car) {
    echo "Name: ", $car->name, "\n";
}
```

Complete objects can be modified and re-saved in the database because they represent a complete record of the associated table. There are other types of queries that do not return complete objects, for example:

```
<?php

$phql = "SELECT c.id, c.name FROM Cars AS c ORDER BY c.name";
$cars = $manager->executeQuery($phql);
foreach ($cars as $car) {
    echo "Name: ", $car->name, "\n";
}
```

We are only requesting some fields in the table, therefore those cannot be considered an entire object, so the returned object is still a resulset of type [Phalcon\Mvc\Model\Resultset\Simple](#). However, each element is a standard object that only contain the two columns that were requested.

These values that don't represent complete objects are what we call scalars. PHQL allows you to query all types of scalars: fields, functions, literals, expressions, etc..:

```
<?php

$phql = "SELECT CONCAT(c.id, ' ', c.name) AS id_name FROM Cars AS c ORDER BY c.name";
$cars = $manager->executeQuery($phql);
foreach ($cars as $car) {
    echo $car->id_name, "\n";
}
```

As we can query complete objects or scalars, we can also query both at once:

```
<?php

$phql = "SELECT c.price*0.16 AS taxes, c.* FROM Cars AS c ORDER BY c.name";
$result = $manager->executeQuery($phql);
```

The result in this case is an object [Phalcon\Mvc\Model\Resultset\Complex](#). This allows access to both complete objects and scalars at once:

```
<?php

foreach ($result as $row) {
    echo "Name: ", $row->cars->name, "\n";
    echo "Price: ", $row->cars->price, "\n";
    echo "Taxes: ", $row->taxes, "\n";
}
```

Scalars are mapped as properties of each “row”, while complete objects are mapped as properties with the name of its related model.

Joins

It's easy to request records from multiple models using PHQL. Most kinds of Joins are supported. As we defined relationships in the models, PHQL adds these conditions automatically:

```
<?php

$phql = "SELECT Cars.name AS car_name, Brands.name AS brand_name FROM Cars JOIN Brands";
$rows = $manager->executeQuery($phql);
foreach ($rows as $row) {
    echo $row->car_name, "\n";
    echo $row->brand_name, "\n";
}
```

By default, an INNER JOIN is assumed. You can specify the type of JOIN in the query:

```
<?php

$phql = "SELECT Cars.*, Brands.* FROM Cars INNER JOIN Brands";
$rows = $manager->executeQuery($phql);

$phql = "SELECT Cars.*, Brands.* FROM Cars LEFT JOIN Brands";
$rows = $manager->executeQuery($phql);

$phql = "SELECT Cars.*, Brands.* FROM Cars LEFT OUTER JOIN Brands";
$rows = $manager->executeQuery($phql);

$phql = "SELECT Cars.*, Brands.* FROM Cars CROSS JOIN Brands";
$rows = $manager->executeQuery($phql);
```

Also is possible set manually the conditions of the JOIN:

```
<?php

$phql = "SELECT Cars.*, Brands.* FROM Cars INNER JOIN Brands ON Brands.id = Cars.brands_id";
$rows = $manager->executeQuery($phql);
```

Also, the joins can be created using multiple tables in the FROM clause:

```
<?php

$phql = "SELECT Cars.*, Brands.* FROM Cars, Brands WHERE Brands.id = Cars.brands_id";
$rows = $manager->executeQuery($phql);
foreach ($rows as $row) {
    echo "Car: ", $row->cars->name, "\n";
    echo "Brand: ", $row->brands->name, "\n";
}
```

If an alias is used to rename the models in the query, those will be used to name the attributes in the every row of the result:

```
<?php

$phql = "SELECT c.*, b.* FROM Cars c, Brands b WHERE b.id = c.brands_id";
$rows = $manager->executeQuery($phql);
foreach ($rows as $row) {
    echo "Car: ", $row->c->name, "\n";
    echo "Brand: ", $row->b->name, "\n";
}
```

When the joined model has a many-to-many relation to the ‘from’ model, the intermediate model is implicitly added to the generated query:

```
<?php

$phql = 'SELECT Brands.name, Songs.name FROM Artists ' .
        'JOIN Songs WHERE Artists.genre = "Trip-Hop"';
$result = $this->modelsManager->query($phql);
```

This code produces the following SQL in MySQL:

```
SELECT `brands`.`name`, `songs`.`name` FROM `artists`
INNER JOIN `albums` ON `albums`.`artists_id` = `artists`.`id`
INNER JOIN `songs` ON `albums`.`songs_id` = `songs`.`id`
WHERE `artists`.`genre` = 'Trip-Hop'
```

Aggregations

The following examples show how to use aggregations in PHQL:

```
<?php

// How much are the prices of all the cars?
$phql = "SELECT SUM(price) AS summatory FROM Cars";
$row = $manager->executeQuery($phql)->getFirst();
echo $row['summatory'];

// How many cars are by each brand?
$phql = "SELECT Cars.brand_id, COUNT(*) FROM Cars GROUP BY Cars.brand_id";
$rows = $manager->executeQuery($phql);
foreach ($rows as $row) {
    echo $row->brand_id, ' ', $row["1"], "\n";
}

// How many cars are by each brand?
$phql = "SELECT Brands.name, COUNT(*) FROM Cars JOIN Brands GROUP BY 1";
$rows = $manager->executeQuery($phql);
foreach ($rows as $row) {
    echo $row->name, ' ', $row["1"], "\n";
}

$phql = "SELECT MAX(price) AS maximum, MIN(price) AS minimum FROM Cars";
$rows = $manager->executeQuery($phql);
foreach ($rows as $row) {
    echo $row["maximum"], ' ', $row["minimum"], "\n";
}

// Count distinct used brands
$phql = "SELECT COUNT(DISTINCT brand_id) AS brandId FROM Cars";
$rows = $manager->executeQuery($phql);
foreach ($rows as $row) {
    echo $row->brandId, "\n";
}
```

Conditions

Conditions allow us to filter the set of records we want to query. The WHERE clause allows to do that:

```
<?php

// Simple conditions
$phql = "SELECT * FROM Cars WHERE Cars.name = 'Lamborghini Espada'";
$cars = $manager->executeQuery($phql);

$phql = "SELECT * FROM Cars WHERE Cars.price > 10000";
$cars = $manager->executeQuery($phql);

$phql = "SELECT * FROM Cars WHERE TRIM(Cars.name) = 'Audi R8'";
$cars = $manager->executeQuery($phql);

$phql = "SELECT * FROM Cars WHERE Cars.name LIKE 'Ferrari%'";
$cars = $manager->executeQuery($phql);

$phql = "SELECT * FROM Cars WHERE Cars.name NOT LIKE 'Ferrari%'";
$cars = $manager->executeQuery($phql);

$phql = "SELECT * FROM Cars WHERE Cars.price IS NULL";
$cars = $manager->executeQuery($phql);

$phql = "SELECT * FROM Cars WHERE Cars.id IN (120, 121, 122)";
$cars = $manager->executeQuery($phql);

$phql = "SELECT * FROM Cars WHERE Cars.id NOT IN (430, 431)";
$cars = $manager->executeQuery($phql);

$phql = "SELECT * FROM Cars WHERE Cars.id BETWEEN 1 AND 100";
$cars = $manager->executeQuery($phql);
```

Also, as part of PHQL, prepared parameters automatically escape the input data, introducing more security:

```
<?php

$phql = "SELECT * FROM Cars WHERE Cars.name = :name:";
$cars = $manager->executeQuery($phql, array("name" => 'Lamborghini Espada'));

$phql = "SELECT * FROM Cars WHERE Cars.name = ?0";
$cars = $manager->executeQuery($phql, array(0 => 'Lamborghini Espada'));
```

2.14.4 Inserting Data

With PHQL it's possible to insert data using the familiar INSERT statement:

```
<?php

// Inserting without columns
$phql = "INSERT INTO Cars VALUES (NULL, 'Lamborghini Espada', "
    . "7, 10000.00, 1969, 'Grand Tourer')";
$manager->executeQuery($phql);

// Specifying columns to insert
$phql = "INSERT INTO Cars (name, brand_id, year, style) "
    . "VALUES ('Lamborghini Espada', 7, 1969, 'Grand Tourer')";
$manager->executeQuery($phql);

// Inserting using placeholders
```

```
$phql = "INSERT INTO Cars (name, brand_id, year, style) "
    . "VALUES (:name:, :brand_id:, :year:, :style)";
$manager->executeQuery($sql,
    array(
        'name'      => 'Lamborghini Espada',
        'brand_id'  => 7,
        'year'       => 1969,
        'style'      => 'Grand Tourer',
    )
);
```

Phalcon doesn't only transform the PHQL statements into SQL. All events and business rules defined in the model are executed as if we created individual objects manually. Let's add a business rule on the model cars. A car cannot cost less than \$ 10,000:

```
<?php

use Phalcon\Mvc\Model;
use Phalcon\Mvc\Model\Message;

class Cars extends Model
{

    public function beforeCreate()
    {
        if ($this->price < 10000) {
            $this->appendMessage(new Message("A car cannot cost less than $ 10,000"));
            return false;
        }
    }
}
```

If we made the following INSERT in the models Cars, the operation will not be successful because the price does not meet the business rule that we implemented. By checking the status of the insertion we can print any validation messages generated internally:

```
<?php

$phql   = "INSERT INTO Cars VALUES (NULL, 'Nissan Versa', 7, 9999.00, 2015, 'Sedan')";
$result = $manager->executeQuery($phql);
if ($result->success() == false) {
    foreach ($result->getMessages() as $message) {
        echo $message->getMessage();
    }
}
```

2.14.5 Updating Data

Updating rows is very similar than inserting rows. As you may know, the instruction to update records is UPDATE. When a record is updated the events related to the update operation will be executed for each row.

```
<?php

// Updating a single column
$phql = "UPDATE Cars SET price = 15000.00 WHERE id = 101";
$manager->executeQuery($phql);
```

```
// Updating multiples columns
$phql = "UPDATE Cars SET price = 15000.00, type = 'Sedan' WHERE id = 101";
$manager->executeQuery($phql);

// Updating multiples rows
$phql = "UPDATE Cars SET price = 7000.00, type = 'Sedan' WHERE brands_id > 5";
$manager->executeQuery($phql);

// Using placeholders
$phql = "UPDATE Cars SET price = ?0, type = ?1 WHERE brands_id > ?2";
$manager->executeQuery($phql, array(
    0 => 7000.00,
    1 => 'Sedan',
    2 => 5
));
```

An UPDATE statement performs the update in two phases:

- First, if the UPDATE has a WHERE clause it retrieves all the objects that match these criteria,
- Second, based on the queried objects it updates/changes the requested attributes storing them to the relational database

This way of operation allows that events, virtual foreign keys and validations take part of the updating process. In summary, the following code:

```
<?php

$phql     = "UPDATE Cars SET price = 15000.00 WHERE id > 101";
$result  = $manager->executeQuery($phql);
if ($result->success() == false) {
    foreach ($result->getMessages() as $message) {
        echo $message->getMessage();
    }
}
```

is somewhat equivalent to:

```
<?php

$messages = null;

$process = function() use (&$messages) {
    foreach (Cars::find("id > 101") as $car) {
        $car->price = 15000;
        if ($car->save() == false) {
            $messages = $car->getMessages();
            return false;
        }
    }
    return true;
};

$success = $process();
```

2.14.6 Deleting Data

When a record is deleted the events related to the delete operation will be executed for each row:

```
<?php

// Deleting a single row
$phql = "DELETE FROM Cars WHERE id = 101";
$manager->executeQuery($phql);

// Deleting multiple rows
$phql = "DELETE FROM Cars WHERE id > 100";
$manager->executeQuery($phql);

// Using placeholders
$phql = "DELETE FROM Cars WHERE id BETWEEN :initial: AND :final:";
$manager->executeQuery(
    $phql,
    array(
        'initial' => 1,
        'final'    => 100
    )
);
```

DELETE operations are also executed in two phases like UPDATEs. To check if the deletion produces any validation messages you should check the status code returned:

```
// Deleting multiple rows
$phql = "DELETE FROM Cars WHERE id > 100";
$result = $manager->executeQuery($phql);
if ($result->success() == false) {
    foreach ($result->getMessages() as $message) {
        echo $message->getMessage();
    }
}
```

2.14.7 Creating queries using the Query Builder

A builder is available to create PHQL queries without the need to write PHQL statements, also providing IDE facilities:

```
<?php

//Getting a whole set
$robots = $this->modelsManager->createBuilder()
    ->from('Robots')
    ->join('RobotsParts')
    ->orderBy('Robots.name')
    ->getQuery()
    ->execute();

//Getting the first row
$robots = $this->modelsManager->createBuilder()
    ->from('Robots')
    ->join('RobotsParts')
    ->orderBy('Robots.name')
    ->getQuery()
    ->getSingleResult();
```

That is the same as:

```
<?php

$phql   = "SELECT Robots.* FROM Robots JOIN RobotsParts p
          ORDER BY Robots.name LIMIT 20";
$result = $manager->executeQuery($phql);
```

More examples of the builder:

```
<?php

// 'SELECT Robots.* FROM Robots';
$builder->from('Robots');

// 'SELECT Robots.*, RobotsParts.* FROM Robots, RobotsParts';
$builder->from(array('Robots', 'RobotsParts'));

// 'SELECT * FROM Robots';
$phql = $builder->columns('*')
              ->from('Robots');

// 'SELECT id FROM Robots';
$builder->columns('id')
          ->from('Robots');

// 'SELECT id, name FROM Robots';
$builder->columns(array('id', 'name'))
          ->from('Robots');

// 'SELECT Robots.* FROM Robots WHERE Robots.name = "Voltron"';
$builder->from('Robots')
          ->where('Robots.name = "Voltron"');

// 'SELECT Robots.* FROM Robots WHERE Robots.id = 100';
$builder->from('Robots')
          ->where(100);

// 'SELECT Robots.* FROM Robots WHERE Robots.type = "virtual" AND Robots.id > 50';
$builder->from('Robots')
          ->where('type = "virtual"')
          ->andWhere('id > 50');

// 'SELECT Robots.* FROM Robots WHERE Robots.type = "virtual" OR Robots.id > 50';
$builder->from('Robots')
          ->where('type = "virtual"')
          ->orWhere('id > 50');

// 'SELECT Robots.* FROM Robots GROUP BY Robots.name';
$builder->from('Robots')
          ->groupBy('Robots.name');

// 'SELECT Robots.* FROM Robots GROUP BY Robots.name, Robots.id';
$builder->from('Robots')
          ->groupBy(array('Robots.name', 'Robots.id'));

// 'SELECT Robots.name, SUM(Robots.price) FROM Robots GROUP BY Robots.name';
$builder->columns(array('Robots.name', 'SUM(Robots.price)'))
          ->from('Robots')
          ->groupBy('Robots.name');
```

```
// 'SELECT Robots.name, SUM(Robots.price) FROM Robots GROUP BY Robots.name HAVING SUM(Robots.price) > 1000';
$builder->columns(array('Robots.name', 'SUM(Robots.price)'))
    ->from('Robots')
    ->groupBy('Robots.name')
    ->having('SUM(Robots.price) > 1000');

// 'SELECT Robots.* FROM Robots JOIN RobotsParts';
$builder->from('Robots')
    ->join('RobotsParts');

// 'SELECT Robots.* FROM Robots JOIN RobotsParts AS p';
$builder->from('Robots')
    ->join('RobotsParts', null, 'p');

// 'SELECT Robots.* FROM Robots JOIN RobotsParts ON Robots.id = RobotsParts.robots_id AS p';
$builder->from('Robots')
    ->join('RobotsParts', 'Robots.id = RobotsParts.robots_id', 'p');

// 'SELECT Robots.* FROM Robots ;
// JOIN RobotsParts ON Robots.id = RobotsParts.robots_id AS p ;
// JOIN Parts ON Parts.id = RobotsParts.parts_id AS t';
$builder->from('Robots')
    ->join('RobotsParts', 'Robots.id = RobotsParts.robots_id', 'p')
    ->join('Parts', 'Parts.id = RobotsParts.parts_id', 't');

// 'SELECT r.* FROM Robots AS r';
$builder->addFrom('Robots', 'r');

// 'SELECT Robots.*, p.* FROM Robots, Parts AS p';
$builder->from('Robots')
    ->addFrom('Parts', 'p');

// 'SELECT r.*, p.* FROM Robots AS r, Parts AS p';
$builder->from(array('r' => 'Robots'))
    ->addFrom('Parts', 'p');

// 'SELECT r.*, p.* FROM Robots AS r, Parts AS p';
$builder->from(array('r' => 'Robots', 'p' => 'Parts'));

// 'SELECT Robots.* FROM Robots LIMIT 10';
$builder->from('Robots')
    ->limit(10);

// 'SELECT Robots.* FROM Robots LIMIT 10 OFFSET 5';
$builder->from('Robots')
    ->limit(10, 5);

// 'SELECT Robots.* FROM Robots WHERE id BETWEEN 1 AND 100';
$builder->from('Robots')
    ->betweenWhere('id', 1, 100);

// 'SELECT Robots.* FROM Robots WHERE id IN (1, 2, 3)';
$builder->from('Robots')
    ->inWhere('id', array(1, 2, 3));

// 'SELECT Robots.* FROM Robots WHERE id NOT IN (1, 2, 3)';
$builder->from('Robots')
    ->notInWhere('id', array(1, 2, 3));
```

```
// 'SELECT Robots.* FROM Robots WHERE name LIKE "%Art%';
$builder->from('Robots')
    ->where('name LIKE :name:', array('name' => '%' . $name . '%'));

// 'SELECT r.* FROM Store\Robots WHERE r.name LIKE "%Art%';
$builder->from(['r' => 'Store\Robots'])
    ->where('r.name LIKE :name:', array('name' => '%' . $name . '%'));
```

Bound Parameters

Bound parameters in the query builder can be set as the query is constructed or past all at once when executing:

```
<?php

//Passing parameters in the query construction
$robots = $this->modelsManager->createBuilder()
    ->from('Robots')
    ->where('name = :name:', array('name' => $name))
    ->andWhere('type = :type:', array('type' => $type))
    ->getQuery()
    ->execute();

//Passing parameters in query execution
$robots = $this->modelsManager->createBuilder()
    ->from('Robots')
    ->where('name = :name:')
    ->andWhere('type = :type:')
    ->getQuery()
    ->execute(array('name' => $name, 'type' => $type));
```

2.14.8 Disallow literals in PHQL

Literals can be disabled in PHQL, this means that directly using strings, numbers and boolean values in PHQL strings will be disallowed. If PHQL statements are created embedding external data on them, this could open the application to potential SQL injections:

```
<?php

$login  = 'voltron';
$phql   = "SELECT * FROM Models\Users WHERE login = '$login'";
$result = $manager->executeQuery($phql);
```

If \$login is changed to ‘ OR “ = ‘, the produced PHQL is:

```
<?php

"SELECT * FROM Models\Users WHERE login = '' OR '' = ''"
```

Which is always true no matter what the login stored in the database is.

If literals are disallowed strings can be used as part of a PHQL statement, thus an exception will be thrown forcing the developer to use bound parameters. The same query can be written in a secure way like this:

```
<?php
```

```
$phql    = "SELECT Robots.* FROM Robots WHERE Robots.name = :name:";  
$result  = $manager->executeQuery($phql, array('name' => $name));
```

You can disallow literals in the following way:

```
<?php  
  
use Phalcon\Mvc\Model;  
  
Model::setup(array('phqlLiterals' => false));
```

Bound parameters can be used even if literals are allowed or not. Disallowing them is just another security decision a developer could take in web applications.

2.14.9 Escaping Reserved Words

PHQL has a few reserved words, if you want to use any of them as attributes or models names, you need to escape those words using the cross-database escaping delimiters '[' and ']':

```
<?php  
  
$phql    = "SELECT * FROM [Update]";  
$result  = $manager->executeQuery($phql);  
  
$phql    = "SELECT id, [Like] FROM Posts";  
$result  = $manager->executeQuery($phql);
```

The delimiters are dynamically translated to valid delimiters depending on the database system where the application is currently running on.

2.14.10 PHQL Lifecycle

Being a high-level language, PHQL gives developers the ability to personalize and customize different aspects in order to suit their needs. The following is the life cycle of each PHQL statement executed:

- The PHQL is parsed and converted into an Intermediate Representation (IR) which is independent of the SQL implemented by database system
- The IR is converted to valid SQL according to the database system associated to the model
- PHQL statements are parsed once and cached in memory. Further executions of the same statement result in a slightly faster execution

2.14.11 Using Raw SQL

A database system could offer specific SQL extensions that aren't supported by PHQL, in this case, a raw SQL can be appropriate:

```
<?php  
  
use Phalcon\Mvc\Model;  
use Phalcon\Mvc\Model\Resultset\Simple as Resultset;  
  
class Robots extends Model  
{  
    public static function findByCreateInterval()
```

```

{
    // A raw SQL statement
    $sql    = "SELECT * FROM robots WHERE id > 0";

    // Base model
    $robot = new Robots();

    // Execute the query
    return new Resultset(null, $robot, $robot->getReadConnection()->query($sql));
}
}

```

If Raw SQL queries are common in your application a generic method could be added to your model:

```

<?php

use Phalcon\Mvc\Model;
use Phalcon\Mvc\Model\Resultset\Simple as Resultset;

class Robots extends Model
{
    public static function findByRawSql($conditions, $params=null)
    {
        // A raw SQL statement
        $sql    = "SELECT * FROM robots WHERE $conditions";

        // Base model
        $robot = new Robots();

        // Execute the query
        return new Resultset(null, $robot, $robot->getReadConnection()->query($sql, $params));
    }
}

```

The above findByRawSql could be used as follows:

```

<?php

$robots = Robots::findByRawSql('id > ?', array(10));

```

2.14.12 Troubleshooting

Some things to keep in mind when using PHQL:

- Classes are case-sensitive, if a class is not defined with the same name as it was created this could lead to an unexpected behavior in operating systems with case-sensitive file systems such as Linux.
- Correct charset must be defined in the connection to bind parameters with success
- Aliased classes aren't replaced by full namespaced classes since this only occurs in PHP code and not inside strings
- If column renaming is enabled avoid using column aliases with the same name as columns to be renamed, this may confuse the query resolver

2.15 Caching in the ORM

Every application is different, we could have models whose data change frequently and others that rarely change. Accessing database systems is often one of the most common bottlenecks in terms of performance. This is due to the complex connection/communication processes that PHP must do in each request to obtain data from the database. Therefore, if we want to achieve good performance we need to add some layers of caching where the application requires it.

This chapter explains the possible points where it is possible to implement caching to improve performance. The framework gives you the tools to implement the cache where you demand of it according to the architecture of your application.

2.15.1 Caching Resultsets

A well established technique to avoid the continuous access to the database is to cache resultsets that don't change frequently using a system with faster access (usually memory).

When `Phalcon\Mvc\Model` requires a service to cache resultsets, it will request it to the Dependency Injector Container with the convention name “modelsCache”.

As Phalcon provides a component to `cache` any kind of data, we'll explain how to integrate it with Models. First, you must register it as a service in the services container:

```
<?php

use Phalcon\Cache\Frontend\Data as FrontendData;
use Phalcon\Cache\Backend\Memcache as BackendMemcache;

// Set the models cache service
$di->set('modelsCache', function() {

    // Cache data for one day by default
    $frontCache = new FrontendData(array(
        "lifetime" => 86400
    ));

    // Memcached connection settings
    $cache = new BackendMemcache($frontCache, array(
        "host" => "localhost",
        "port" => "11211"
    ));

    return $cache;
});
```

You have complete control in creating and customizing the cache before being used by registering the service as an anonymous function. Once the cache setup is properly defined you could cache resultsets as follows:

```
<?php

// Get products without caching
$products = Products::find();

// Just cache the resultset. The cache will expire in 1 hour (3600 seconds)
$products = Products::find(array(
    "cache" => array("key" => "my-cache")
));
```

```
// Cache the resultset for only for 5 minutes
$products = Products::find(array(
    "cache" => array("key" => "my-cache", "lifetime" => 300)
));

// Using a custom cache
$products = Products::find(array("cache" => $myCache));
```

Caching could be also applied to resultsets generated using relationships:

```
<?php

// Query some post
$post      = Post::findFirst();

// Get comments related to a post, also cache it
$comments = $post->getComments(array(
    "cache" => array("key" => "my-key")
));

// Get comments related to a post, setting lifetime
$comments = $post->getComments(array(
    "cache" => array("key" => "my-key", "lifetime" => 3600)
));
```

When a cached resultset needs to be invalidated, you can simply delete it from the cache using the previously specified key.

Note that not all resultsets must be cached. Results that change very frequently should not be cached since they are invalidated very quickly and caching in that case impacts performance. Additionally, large datasets that do not change frequently could be cached, but that is a decision that the developer has to make based on the available caching mechanism and whether the performance impact to simply retrieve that data in the first place is acceptable.

2.15.2 Overriding find/findFirst

As seen above, these methods are available in models that inherit `Phalcon\Mvc\Model`:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public static function find($parameters=null)
    {
        return parent::find($parameters);
    }

    public static function findFirst($parameters=null)
    {
        return parent::findFirst($parameters);
    }
}
```

By doing this, you're intercepting all the calls to these methods, this way, you can add a cache layer or run the query if

there is no cache. For example, a very basic cache implementation, uses a static property to avoid that a record would be queried several times in a same request:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    protected static $_cache = array();

    /**
     * Implement a method that returns a string key based
     * on the query parameters
     */
    protected static function _createKey($parameters)
    {
        $uniqueKey = array();
        foreach ($parameters as $key => $value) {
            if (is_scalar($value)) {
                $uniqueKey[] = $key . ':' . $value;
            } else {
                if (is_array($value)) {
                    $uniqueKey[] = $key . ':' . self::_createKey($value) . ']';
                }
            }
        }
        return join(',', $uniqueKey);
    }

    public static function find($parameters=null)
    {

        //Create an unique key based on the parameters
        $key = self::_createKey($parameters);

        if (!isset(self::$_cache[$key])) {
            //Store the result in the memory cache
            self::$_cache[$key] = parent::find($parameters);
        }

        //Return the result in the cache
        return self::$_cache[$key];
    }

    public static function findFirst($parameters=null)
    {
        // ...
    }
}
```

Access the database is several times slower than calculate a cache key, you're free in implement the key generation strategy you find better for your needs. Note that a good key avoids collisions as much as possible, this means that different keys returns unrelated records to the find parameters.

In the above example, we used a cache in memory, it is useful as a first level cache. Once we have the memory cache, we can implement a second level cache layer like APC/XCache or a NoSQL database:

```
<?php

public static function find($parameters=null)
{
    //Create an unique key based on the parameters
    $key = self::__createKey($parameters);

    if (!isset(self::$_cache[$key])) {
        //We're using APC as second cache
        if (apc_exists($key)) {
            $data = apc_fetch($key);

            //Store the result in the memory cache
            self::$_cache[$key] = $data;
        }

        return $data;
    }

    //There are no memory or apc cache
    $data = parent::find($parameters);

    //Store the result in the memory cache
    self::$_cache[$key] = $data;

    //Store the result in APC
    apc_store($key, $data);

    return $data;
}

//Return the result in the cache
return self::$_cache[$key];
}
```

This gives you full control on how the the caches must be implemented for each model, if this strategy is common to several models you can create a base class for all of them:

```
<?php

use Phalcon\Mvc\Model;

class CacheableModel extends Model
{
    protected static function __createKey($parameters)
    {
        // .. create a cache key based on the parameters
    }

    public static function find($parameters=null)
    {
        //... custom caching strategy
    }

    public static function findFirst($parameters=null)
```

```
{  
    //... custom caching strategy  
}  
}
```

Then use this class as base class for each ‘Cacheable’ model:

```
<?php  
  
class Robots extends CacheableModel  
{  
}
```

2.15.3 Forcing Cache

Earlier we saw how Phalcon\Mvc\Model has a built-in integration with the caching component provided by the framework. To make a record/resultset cacheable we pass the key ‘cache’ in the array of parameters:

```
<?php  
  
// Cache the resultset for only for 5 minutes  
$products = Products::find(array(  
    "cache" => array("key" => "my-cache", "lifetime" => 300)  
));
```

This gives us the freedom to cache specific queries, however if we want to cache globally every query performed over the model, we can override the find/findFirst method to force every query to be cached:

```
<?php  
  
use Phalcon\Mvc\Model;  
  
class Robots extends Model  
{  
  
    protected static function _createKey($parameters)  
    {  
        // .. create a cache key based on the parameters  
    }  
  
    public static function find($parameters=null)  
    {  
  
        //Convert the parameters to an array  
        if (!is_array($parameters)) {  
            $parameters = array($parameters);  
        }  
  
        //Check if a cache key wasn't passed  
        //and create the cache parameters  
        if (!isset($parameters['cache'])) {  
            $parameters['cache'] = array(  
                "key"      => self::_createKey($parameters),  
                "lifetime" => 300  
            );  
        }  
    }  
}
```

```

        return parent::find($parameters);
    }

    public static function findFirst($parameters=null)
    {
        //...
    }
}

```

2.15.4 Caching PHQL Queries

All queries in the ORM, no matter how high level syntax we used to create them are handled internally using PHQL. This language gives you much more freedom to create all kinds of queries. Of course these queries can be cached:

```

<?php

$phql = "SELECT * FROM Cars WHERE name = :name:";

$query = $this->modelsManager->createQuery($phql);

$query->cache(array(
    "key"      => "cars-by-name",
    "lifetime" => 300
));

$cars = $query->execute(array(
    'name' => 'Audi'
));

```

If you don't want to use the implicit cache just save the resulset into your favorite cache backend:

```

<?php

$phql = "SELECT * FROM Cars WHERE name = :name:";

$cars = $this->modelsManager->executeQuery($phql, array(
    'name' => 'Audi'
));

apc_store('my-cars', $cars);

```

2.15.5 Reusable Related Records

Some models may have relationships to other models. This allows us to easily check the records that relate to instances in memory:

```

<?php

//Get some invoice
$invoice = Invoices::findFirst();

//Get the customer related to the invoice
$customer = $invoice->customer;

```

```
//Print his/her name
echo $customer->name, "\n";
```

This example is very simple, a customer is queried and can be used as required, for example, to show its name. This also applies if we retrieve a set of invoices to show customers that correspond to these invoices:

```
<?php

//Get a set of invoices
// SELECT * FROM invoices;
foreach (Invoices::find() as $invoice) {

    //Get the customer related to the invoice
    // SELECT * FROM customers WHERE id = ?;
    $customer = $invoice->customer;

    //Print his/her name
    echo $customer->name, "\n";
}
```

A customer may have one or more bills, this means that the customer may be unnecessarily more than once. To avoid this, we could mark the relationship as reusable, this way, we tell the ORM to automatically reuse the records instead of re-querying them again and again:

```
<?php

use Phalcon\Mvc\Model;

class Invoices extends Model
{

    public function initialize()
    {
        $this->belongsTo("customers_id", "Customer", "id", array(
            'reusable' => true
        ));
    }
}
```

This cache works in memory only, this means that cached data are released when the request is terminated. You can add a more sophisticated cache for this scenario overriding the models manager:

```
<?php

use Phalcon\Mvc\Model\Manager as ModelManager;

class CustomModelsManager extends ModelManager
{

    /**
     * Returns a reusable object from the cache
     *
     * @param string $modelName
     * @param string $key
     * @return object
     */
    public function getReusableRecords($modelName, $key) {
```

```

//If the model is Products use the APC cache
if ($modelName == 'Products'){
    return apc_fetch($key);
}

//For the rest, use the memory cache
return parent::getReusableRecords($modelName, $key);
}

/**
 * Stores a reusable record in the cache
 *
 * @param string $modelName
 * @param string $key
 * @param mixed $records
 */
public function setReusableRecords($modelName, $key, $records) {

    //If the model is Products use the APC cache
    if ($modelName == 'Products'){
        apc_store($key, $records);
        return;
    }

    //For the rest, use the memory cache
    parent::setReusableRecords($modelName, $key, $records);
}
}

```

Do not forget to register the custom models manager in the DI:

```

<?php

$di->setShared('modelsManager', function() {
    return new CustomModelsManager();
});

```

2.15.6 Caching Related Records

When a related record is queried, the ORM internally builds the appropriate condition and gets the required records using find/findFirst in the target model according to the following table:

Type	Description Implicit Method
Belongs-To	Returns a model instance of the related record directly findFirst
Has-One	Returns a model instance of the related record directly findFirst
Has-Many	Returns a collection of model instances of the referenced model find

This means that when you get a related record you could intercept how these data are obtained by implementing the corresponding method:

```

<?php

//Get some invoice
$invoice = Invoices::findFirst();

//Get the customer related to the invoice
$customer = $invoice->customer; // Invoices::findFirst('...');

```

```
//Same as above
$customer = $invoice->getCustomer(); // Invoices::findFirst('...');
```

Accordingly, we could replace the `findFirst` method in the model `Invoices` and implement the cache we consider most appropriate:

```
<?php

use Phalcon\Mvc\Model;

class Invoices extends Model
{

    public static function findFirst($parameters=null)
    {
        //... custom caching strategy
    }
}
```

2.15.7 Caching Related Records Recursively

In this scenario, we assume that everytime we query a result we also retrieve their associated records. If we store the records found together with their related entities perhaps we could reduce a bit the overhead required to obtain all entities:

```
<?php

use Phalcon\Mvc\Model;

class Invoices extends Model
{

    protected static function _createKey($parameters)
    {
        // .. create a cache key based on the parameters
    }

    protected static function _getCache($key)
    {
        // returns data from a cache
    }

    protected static function _setCache($key)
    {
        // stores data in the cache
    }

    public static function find($parameters=null)
    {
        //Create a unique key
        $key      = self::_createKey($parameters);

        //Check if there are data in the cache
        $results = self::_getCache($key);

        // Valid data is an object
    }
}
```

```

if (is_object($results)) {
    return $results;
}

$results = array();

$invoices = parent::find($parameters);
foreach ($invoices as $invoice) {

    //Query the related customer
    $customer = $invoice->customer;

    //Assign it to the record
    $invoice->customer = $customer;

    $results[] = $invoice;
}

//Store the invoices in the cache + their customers
self::_setCache($key, $results);

return $results;
}

public function initialize()
{
    // add relations and initialize other stuff
}
}

```

Getting the invoices from the cache already obtains the customer data in just one hit, reducing the overall overhead of the operation. Note that this process can also be performed with PHQL following an alternative solution:

```

<?php

use Phalcon\Mvc\Model;

class Invoices extends Model
{

    public function initialize()
    {
        // add relations and initialize other stuff
    }

    protected static function _createKey($conditions, $params)
    {
        // .. create a cache key based on the parameters
    }

    public function getInvoicesCustomers($conditions, $params=null)
    {
        $phql = "SELECT Invoices.*, Customers.*  

                FROM Invoices JOIN Customers WHERE " . $conditions;

        $query = $this->getModelsManager()->executeQuery($phql);

        $query->cache(array(

```

```
        "key"      => self::$_createKey($conditions, $params),
        "lifetime" => 300
    ));

    return $query->execute($params);
}

}
```

2.15.8 Caching based on Conditions

In this scenario, the cache is implemented conditionally according to current conditions received. According to the range where the primary key is located we choose a different cache backend:

Type	Cache Backend
1 - 10000	mongo1
10000 - 20000	mongo2
> 20000	mongo3

The easiest way is adding an static method to the model that chooses the right cache to be used:

```
<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{

    public static function queryCache($initial, $final)
    {
        if ($initial >= 1 && $final < 10000) {
            return self::find(array(
                'id' >= ' ' . $initial . ' AND id <= ' . $final,
                'cache' => array('service' => 'mongo1')
            ));
        }
        if ($initial >= 10000 && $final <= 20000) {
            return self::find(array(
                'id' >= ' ' . $initial . ' AND id <= ' . $final,
                'cache' => array('service' => 'mongo2')
            ));
        }
        if ($initial > 20000) {
            return self::find(array(
                'id' >= ' ' . $initial,
                'cache' => array('service' => 'mongo3')
            ));
        }
    }
}
```

This approach solves the problem, however, if we want to add other parameters such orders or conditions we would have to create a more complicated method. Additionally, this method does not work if the data is obtained using related records or a find/findFirst:

```
<?php

$robots = Robots::find('id < 1000');
$robots = Robots::find('id > 100 AND type = "A"');
$robots = Robots::find('(id > 100 AND type = "A") AND id < 2000');

$robots = Robots::find(array(
    '(id > ?0 AND type = "A") AND id < ?1',
    'bind' => array(100, 2000),
    'order' => 'type'
));
)
```

To achieve this we need to intercept the intermediate representation (IR) generated by the PHQL parser and thus customize the cache everything possible:

The first is create a custom builder, so we can generate a totally customized query:

```
<?php

use Phalcon\Mvc\Model\Query\Builder as QueryBuilder;

class CustomQueryBuilder extends QueryBuilder
{

    public function getQuery()
    {
        $query = new CustomQuery($this->getPhql());
        $query->setDI($this->getDI());
        return $query;
    }

}
```

Instead of directly returning a `Phalcon\Mvc\Model\Query`, our custom builder returns a `CustomQuery` instance, this class looks like:

```
<?php

use Phalcon\Mvc\Model\Query as ModelQuery;

class CustomQuery extends ModelQuery
{

    /**
     * The execute method is overridden
     */
    public function execute($params=null, $types=null)
    {
        //Parse the intermediate representation for the SELECT
        $ir = $this->parse();

        //Check if the query has conditions
        if (isset($ir['where'])) {

            //The fields in the conditions can have any order
            //We need to recursively check the conditions tree
            //to find the info we're looking for
            $visitor = new CustomNodeVisitor();
        }
    }
}
```

```
//Recursively visits the nodes
$visitor->visit($ir['where']);

$initial = $visitor->getInitial();
$final   = $visitor->getFinal();

//Select the cache according to the range
//...

//Check if the cache has data
//...
}

//Execute the query
$result = $this->_executeSelect($ir, $params, $types);

//cache the result
//...

return $result;
}

}
```

Implementing a helper (CustomNodeVisitor) that recursively checks the conditions looking for fields that tell us the possible range to be used in the cache:

```
<?php

class CustomNodeVisitor
{

    protected $_initial = 0;

    protected $_final = 25000;

    public function visit($node)
    {
        switch ($node['type']) {

            case 'binary-op':

                $left  = $this->visit($node['left']);
                $right = $this->visit($node['right']);
                if (!$left || !$right) {
                    return false;
                }

                if ($left=='id') {
                    if ($node['op'] == '>') {
                        $this->_initial = $right;
                    }
                    if ($node['op'] == '=') {
                        $this->_initial = $right;
                    }
                    if ($node['op'] == '>=') {
                        $this->_initial = $right;
                    }
                }
        }
    }
}
```

```

        if ($node['op'] == '<') {
            $this->_final = $right;
        }
        if ($node['op'] == '<=') {
            $this->_final = $right;
        }
    }
    break;

case 'qualified':
    if ($node['name'] == 'id') {
        return 'id';
    }
    break;

case 'literal':
    return $node['value'];

default:
    return false;
}
}

public function getInitial()
{
    return $this->_initial;
}

public function getFinal()
{
    return $this->_final;
}
}

```

Finally, we can replace the find method in the Robots model to use the custom classes we've created:

```

<?php

use Phalcon\Mvc\Model;

class Robots extends Model
{
    public static function find($parameters=null)
    {

        if (!is_array($parameters)) {
            $parameters = array($parameters);
        }

        $builder = new CustomQueryBuilder($parameters);
        $builder->from(get_called_class());

        if (isset($parameters['bind'])) {
            return $builder->getQuery()->execute($parameters['bind']);
        } else {
            return $builder->getQuery()->execute();
        }
    }
}

```

```
    }
}
```

2.15.9 Caching of PHQL planning

As well as most moderns database systems PHQL internally caches the execution plan, if the same statement is executed several times PHQL reuses the previously generated plan improving performance, for a developer to take better advantage of this is highly recommended build all your SQL statements passing variable parameters as bound parameters:

```
<?php

for ($i = 1; $i <= 10; $i++) {

    $phql   = "SELECT * FROM Store\Robots WHERE id = " . $i;
    $robots = $this->modelsManager->executeQuery($phql);

    //...
}
```

In the above example, ten plans were generated increasing the memory usage and processing in the application. Rewriting the code to take advantage of bound parameters reduces the processing by both ORM and database system:

```
<?php

$phql = "SELECT * FROM Store\Robots WHERE id = ?0";

for ($i = 1; $i <= 10; $i++) {

    $robots = $this->modelsManager->executeQuery($phql, array($i));

    //...
}
```

Performance can be also improved reusing the PHQL query:

```
<?php

$phql = "SELECT * FROM Store\Robots WHERE id = ?0";
$query = $this->modelsManager->createQuery($phql);

for ($i = 1; $i <= 10; $i++) {

    $robots = $query->execute($phql, array($i));

    //...
}
```

Execution plans for queries involving [prepared statements](#) are also cached by most database systems reducing the overall execution time, also protecting your application against [SQL Injections](#).

2.16 ODM (Object-Document Mapper)

In addition to its ability to [map tables](#) in relational databases, Phalcon can map documents from NoSQL databases. The ODM offers a CRUD functionality, events, validations among other services.

Due to the absence of SQL queries and planners, NoSQL databases can see real improvements in performance using the Phalcon approach. Additionally, there are no SQL building reducing the possibility of SQL injections.

The following NoSQL databases are supported:

Name	Description
MongoDB	MongoDB is a scalable, high-performance, open source NoSQL database.

2.16.1 Creating Models

A model is a class that extends from `Phalcon\Mvc\Collection`. It must be placed in the models directory. A model file must contain a single class; its class name should be in camel case notation:

```
<?php

use Phalcon\Mvc\Collection;

class Robots extends Collection
{}
```

If you're using PHP 5.4/5.5 is recommended declare each column that makes part of the model in order to save memory and reduce the memory allocation.

By default model "Robots" will refer to the collection "robots". If you want to manually specify another name for the mapping collection, you can use the `getSource()` method:

```
<?php

use Phalcon\Mvc\Collection;

class Robots extends Collection
{
    public function getSource()
    {
        return "the_robots";
    }
}
```

2.16.2 Understanding Documents To Objects

Every instance of a model represents a document in the collection. You can easily access collection data by reading object properties. For example, for a collection "robots" with the documents:

```
$ mongo test
MongoDB shell version: 1.8.2
connecting to: test
> db.robots.find()
{ "_id" : ObjectId("508735512d42b8c3d15ec4e1"), "name" : "Astro Boy", "year" : 1952,
  "type" : "mechanical" }
{ "_id" : ObjectId("5087358f2d42b8c3d15ec4e2"), "name" : "Bender", "year" : 1999,
  "type" : "mechanical" }
{ "_id" : ObjectId("508735d32d42b8c3d15ec4e3"), "name" : "Wall-E", "year" : 2008 }
>
```

2.16.3 Models in Namespaces

Namespaces can be used to avoid class name collision. In this case it is necessary to indicate the name of the related collection using getSource:

```
<?php

namespace Store\Toys;

use Phalcon\Mvc\Collection;

class Robots extends Collection
{

    public function getSource()
    {
        return "robots";
    }

}
```

You could find a certain document by its id and then print its name:

```
<?php

// Find record with _id = "5087358f2d42b8c3d15ec4e2"
$robot = Robots::findByID("5087358f2d42b8c3d15ec4e2");

// Prints "Bender"
echo $robot->name;
```

Once the record is in memory, you can make modifications to its data and then save changes:

```
<?php

$robot = Robots::findFirst(array(
    array('name' => 'Astroy Boy')
));
$robot->name = "Voltron";
$robot->save();
```

2.16.4 Setting a Connection

Connections are retrieved from the services container. By default, Phalcon tries to find the connection in a service called “mongo”:

```
<?php

// Simple database connection to localhost
$di->set('mongo', function() {
    $mongo = new MongoClient();
    return $mongo->selectDB("store");
}, true);

// Connecting to a domain socket, falling back to localhost connection
$di->set('mongo', function() {
    $mongo = new MongoClient("mongodb://tmp/mongodb-27017.sock,localhost:27017");
```

```

    return $mongo->selectDB("store");
}, true);

```

2.16.5 Finding Documents

As Phalcon\Mvc\Collection relies on the Mongo PHP extension you have the same facilities to query documents and convert them transparently to model instances:

```

<?php

// How many robots are there?
$robots = Robots::find();
echo "There are ", count($robots), "\n";

// How many mechanical robots are there?
$robots = Robots::find(array(
    array("type" => "mechanical")
));
echo "There are ", count($robots), "\n";

// Get and print mechanical robots ordered by name upward
$robots = Robots::find(array(
    array("type" => "mechanical"),
    "sort" => array("name" => 1)
));
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}

// Get first 100 mechanical robots ordered by name
$robots = Robots::find(array(
    array("type" => "mechanical"),
    "sort" => array("name" => 1),
    "limit" => 100
));
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}

```

You could also use the `findFirst()` method to get only the first record matching the given criteria:

```

<?php

// What's the first robot in robots collection?
$robot = Robots::findFirst();
echo "The robot name is ", $robot->name, "\n";

// What's the first mechanical robot in robots collection?
$robot = Robots::findFirst(array(
    array("type" => "mechanical")
));
echo "The first mechanical robot name is ", $robot->name, "\n";

```

Both `find()` and `findFirst()` methods accept an associative array specifying the search criteria:

```
<?php

// First robot where type = "mechanical" and year = "1999"
$robot = Robots::findFirst(array(
    "conditions" => array(
        "type" => "mechanical",
        "year" => "1999"
    )
));

// All virtual robots ordered by name downward
$robots = Robots::find(array(
    "conditions" => array("type" => "virtual"),
    "sort"         => array("name" => -1)
));
)
```

The available query options are:

Parameter	Description	Example
conditions	Search conditions for the find operation. Is used to extract only those records that fulfill a specified criterion. By default Phalcon_model assumes the first parameter are the conditions.	"conditions" => array('\$gt' => 1990)
fields	Returns specific columns instead of the full fields in the collection. When using this option an incomplete object is returned	"fields" => array('name' => true)
sort	It's used to sort the resultset. Use one or more fields as each element in the array, 1 means ordering upwards, -1 downward	"sort" => array("name" => -1, "status" => 1)
limit	Limit the results of the query to results to certain range	"limit" => 10
skip	Skips a number of results	"skip" => 50

If you have experience with SQL databases, you may want to check the [SQL to Mongo Mapping Chart](#).

2.16.6 Aggregations

A model can return calculations using [aggregation framework](#) provided by Mongo. The aggregated values are calculate without having to use MapReduce. With this option is easy perform tasks such as totaling or averaging field values:

```
<?php

$data = Article::aggregate(array(
    array(
        '$project' => array('category' => 1)
    ),
    array(
        '$group' => array(
            '_id' => array('category' => '$category'),
            'id'   => array('$max' => '$_id')
        )
    )
));
```

2.16.7 Creating Updating/Records

The method `Phalcon\Mvc\Collection::save()` allows you to create/update documents according to whether they already exist in the collection associated with a model. The ‘`save`’ method is called internally by the `create` and `update` methods of `Phalcon\Mvc\Collection`.

Also the method executes associated validators and events that are defined in the model:

```
<?php

$robot      = new Robots();
$robot->type = "mechanical";
$robot->name = "Astro Boy";
$robot->year = 1952;
if ($robot->save() == false) {
    echo "Umh, We can't store robots right now: \n";
    foreach ($robot->getMessages() as $message) {
        echo $message, "\n";
    }
} else {
    echo "Great, a new robot was saved successfully!";
}
```

The “`_id`” property is automatically updated with the `Mongoid` object created by the driver:

```
<?php

$robot->save();
echo "The generated id is: ", $robot->getId();
```

Validation Messages

`Phalcon\Mvc\Collection` has a messaging subsystem that provides a flexible way to output or store the validation messages generated during the insert/update processes.

Each message consists of an instance of the class `Phalcon\Mvc\Model\Message`. The set of messages generated can be retrieved with the method `getMessages()`. Each message provides extended information like the field name that generated the message or the message type:

```
<?php

if ($robot->save() == false) {
    foreach ($robot->getMessages() as $message) {
        echo "Message: ", $message->getMessage();
        echo "Field: ", $message->getField();
        echo "Type: ", $message->getType();
    }
}
```

Validation Events and Events Manager

Models allow you to implement events that will be thrown when performing an insert or update. They help define business rules for a certain model. The following are the events supported by `Phalcon\Mvc\Collection` and their order of execution:

Operation	Name	Can stop operation?	Explanation
Inserting/Updating	beforeValidation	YES	Is executed before the validation process and the final insert/update to the database
Inserting	beforeValidationOnCreate	YES	Is executed before the validation process only when an insertion operation is being made
Updating	beforeValidationOnUpdate	YES	Is executed before the fields are validated for not nulls or foreign keys when an updating operation is being made
Inserting/Updating	onValidationFails	YES (already stopped)	Is executed before the validation process only when an insertion operation is being made
Inserting	afterValidationOnCreate	YES	Is executed after the validation process when an insertion operation is being made
Updating	afterValidationOnUpdate	YES	Is executed after the validation process when an updating operation is being made
Inserting/Updating	afterValidation	YES	Is executed after the validation process
Inserting/Updating	beforeSave	YES	Runs before the required operation over the database system
Updating	beforeUpdate	YES	Runs before the required operation over the database system only when an updating operation is being made
Inserting	beforeCreate	YES	Runs before the required operation over the database system only when an inserting operation is being made
Updating	afterUpdate	NO	Runs after the required operation over the database system only when an updating operation is being made
Inserting	afterCreate	NO	Runs after the required operation over the database system only when an inserting operation is being made
Inserting/Updating	afterSave	NO	Runs after the required operation over the database system

To make a model to react to an event, we must implement a method with the same name of the event:

```
<?php

use Phalcon\Mvc\Collection;

class Robots extends Collection
{

    public function beforeValidationOnCreate()
    {
        echo "This is executed before creating a Robot!";
    }

}
```

Events can be useful to assign values before performing an operation, for example:

```
<?php

use Phalcon\Mvc\Collection;

class Products extends Collection
{

    public function beforeCreate()
    {
```

```

    // Set the creation date
    $this->created_at = date('Y-m-d H:i:s');
}

public function beforeUpdate()
{
    // Set the modification date
    $this->modified_in = date('Y-m-d H:i:s');
}

}

```

Additionally, this component is integrated with `Phalcon\Events\Manager`, this means we can create listeners that run when an event is triggered.

```

<?php

use Phalcon\Events\Manager as EventsManager;

$eventsManager = new EventsManager();

//Attach an anonymous function as a listener for "model" events
$eventsManager->attach('collection', function($event, $robot) {
    if ($event->getType() == 'beforeSave') {
        if ($robot->name == 'Scooby Doo') {
            echo "Scooby Doo isn't a robot!";
            return false;
        }
    }
    return true;
});

$robot      = new Robots();
$robot->setEventsManager($eventsManager);
$robot->name = 'Scooby Doo';
$robot->year = 1969;
$robot->save();

```

In the example given above the `EventsManager` only acted as a bridge between an object and a listener (the anonymous function). If we want all objects created in our application use the same `EventsManager`, then we need to assign this to the `Models Manager`:

```

<?php

use Phalcon\Events\Manager as EventsManager;
use Phalcon\Mvc\Collection\Manager as CollectionManager;

//Registering the collectionManager service
$di->set('collectionManager', function() {

    $eventsManager = new EventsManager();

    // Attach an anonymous function as a listener for "model" events
    $eventsManager->attach('collection', function($event, $model) {
        if (get_class($model) == 'Robots') {
            if ($event->getType() == 'beforeSave') {
                if ($model->name == 'Scooby Doo') {
                    echo "Scooby Doo isn't a robot!";
                    return false;
                }
            }
        }
    });
});

```

```
        }
    }
    return true;
});

// Setting a default EventsManager
$modelsManager = new CollectionManager();
$modelsManager->setEventsManager($eventsManager);
return $modelsManager;

}, true);
```

Implementing a Business Rule

When an insert, update or delete is executed, the model verifies if there are any methods with the names of the events listed in the table above.

We recommend that validation methods are declared protected to prevent that business logic implementation from being exposed publicly.

The following example implements an event that validates the year cannot be smaller than 0 on update or insert:

```
<?php

use Phalcon\Mvc\Collection;

class Robots extends Collection
{

    public function beforeSave()
    {
        if ($this->year < 0) {
            echo "Year cannot be smaller than zero!";
            return false;
        }
    }
}
```

Some events return false as an indication to stop the current operation. If an event doesn't return anything, `Phalcon\Mvc\Collection` will assume a true value.

Validating Data Integrity

`Phalcon\Mvc\Collection` provides several events to validate data and implement business rules. The special “validation” event allows us to call built-in validators over the record. Phalcon exposes a few built-in validators that can be used at this stage of validation.

The following example shows how to use it:

```
<?php

use Phalcon\Mvc\Collection;
use Phalcon\Mvc\Model\Validator\InclusionIn;
use Phalcon\Mvc\Model\Validator\Numericality;
```

```

class Robots extends Collection
{

    public function validation()
    {

        $this->validate(new InclusionIn(
            array(
                "field" => "type",
                "message" => "Type must be: mechanical or virtual",
                "domain" => array("Mechanical", "Virtual")
            )
        ));

        $this->validate(new Numericality(
            array(
                "field" => "price",
                "message" => "Price must be numeric"
            )
        ));

        return $this->validationHasFailed() != true;
    }

}

```

The example given above performs a validation using the built-in validator “InclusionIn”. It checks the value of the field “type” in a domain list. If the value is not included in the method, then the validator will fail and return false. The following built-in validators are available:

Name	Explanation	Example
Email	Validates that field contains a valid email format	Example
ExclusionIn	Validates that a value is not within a list of possible values	Example
InclusionIn	Validates that a value is within a list of possible values	Example
Numericality	Validates that a field has a numeric format	Example
Regex	Validates that the value of a field matches a regular expression	Example
StringLength	Validates the length of a string	Example

In addition to the built-in validators, you can create your own validators:

```

<?php

use \Phalcon\Mvc\Model\Validator as CollectionValidator;

class UrlValidator extends CollectionValidator
{

    public function validate($model)
    {
        $field = $this->getOption('field');

        $value = $model->$field;
        $filtered = filter_var($value, FILTER_VALIDATE_URL);
        if (!$filtered) {
            $this->appendMessage("The URL is invalid", $field, "UrlValidator");
            return false;
        }
        return true;
    }
}

```

```
    }  
}
```

Adding the validator to a model:

```
<?php  
  
use Phalcon\Mvc\Collection;  
  
class Customers extends Collection  
{  
  
    public function validation()  
    {  
        $this->validate(new UrlValidator(array(  
            "field" => "url",  
        )));  
        if ($this->validationHasFailed() == true) {  
            return false;  
        }  
    }  
}
```

The idea of creating validators is make them reusable across several models. A validator can also be as simple as:

```
<?php  
  
use Phalcon\Mvc\Collection;  
use Phalcon\Mvc\Model\Message as ModelMessage;  
  
class Robots extends Collection  
{  
  
    public function validation()  
    {  
        if ($this->type == "Old") {  
            $message = new ModelMessage(  
                "Sorry, old robots are not allowed anymore",  
                "type",  
                "MyType"  
            );  
            $this->appendMessage($message);  
            return false;  
        }  
        return true;  
    }  
}
```

2.16.8 Deleting Records

The method `Phalcon\Mvc\Collection::delete()` allows to delete a document. You can use it as follows:

```
<?php  
  
$robot = Robots::findFirst();
```

```

if ($robot != false) {
    if ($robot->delete() == false) {
        echo "Sorry, we can't delete the robot right now: \n";
        foreach ($robot->getMessages() as $message) {
            echo $message, "\n";
        }
    } else {
        echo "The robot was deleted successfully!";
    }
}

```

You can also delete many documents by traversing a resultset with a foreach:

```

<?php

$robots = Robots::find(array(
    array("type" => "mechanical")
));
foreach ($robots as $robot) {
    if ($robot->delete() == false) {
        echo "Sorry, we can't delete the robot right now: \n";
        foreach ($robot->getMessages() as $message) {
            echo $message, "\n";
        }
    } else {
        echo "The robot was deleted successfully!";
    }
}

```

The following events are available to define custom business rules that can be executed when a delete operation is performed:

Operation	Name	Can stop operation?	Explanation
Deleting	beforeDelete	YES	Runs before the delete operation is made
Deleting	afterDelete	NO	Runs after the delete operation was made

2.16.9 Validation Failed Events

Another type of events is available when the data validation process finds any inconsistency:

Operation	Name	Explanation
Insert or Update	notSave	Triggered when the insert/update operation fails for any reason
Insert, Delete or Update	onValidationFails	Triggered when any data manipulation operation fails

2.16.10 Implicit Ids vs. User Primary Keys

By default Phalcon\Mvc\Collection assumes that the `_id` attribute is automatically generated using `MongoIds`. If a model uses custom primary keys this behavior can be overridden:

```

<?php

use Phalcon\Mvc\Collection;

class Robots extends Collection
{
    public function initialize()
}

```

```
{  
    $this->useImplicitObjectIds(false);  
}  
}
```

2.16.11 Setting multiple databases

In Phalcon, all models can belong to the same database connection or have an individual one. Actually, when `Phalcon\Mvc\Collection` needs to connect to the database it requests the “mongo” service in the application’s services container. You can overwrite this service setting it in the initialize method:

```
<?php  
  
// This service returns a mongo database at 192.168.1.100  
$di->set('mongo1', function() {  
    $mongo = new MongoClient("mongodb://scott:nekhen@192.168.1.100");  
    return $mongo->selectDB("management");  
, true);  
  
// This service returns a mongo database at localhost  
$di->set('mongo2', function() {  
    $mongo = new MongoClient("mongodb://localhost");  
    return $mongo->selectDB("invoicing");  
, true);
```

Then, in the Initialize method, we define the connection service for the model:

```
<?php  
  
use Phalcon\Mvc\Collection;  
  
class Robots extends Collection  
{  
    public function initialize()  
    {  
        $this->setConnectionService('mongo1');  
    }  
}
```

2.16.12 Injecting services into Models

You may be required to access the application services within a model, the following example explains how to do that:

```
<?php  
  
use Phalcon\Mvc\Collection;  
  
class Robots extends Collection  
{  
  
    public function notSave()  
    {  
        // Obtain the flash service from the DI container  
        $flash = $this->getDI()->getShared('flash');
```

```
// Show validation messages
foreach ($this->getMessages() as $message) {
    $flash->error((string) $message);
}
}
```

The “notSave” event is triggered whenever a “creating” or “updating” action fails. We’re flashing the validation messages obtaining the “flash” service from the DI container. By doing this, we don’t have to print messages after each saving.

2.17 Using Views

Views represent the user interface of your application. Views are often HTML files with embedded PHP code that perform tasks related solely to the presentation of the data. Views handle the job of providing data to the web browser or other tool that is used to make requests from your application.

`Phalcon\Mvc\View` and `Phalcon\Mvc\View\Simple` are responsible for managing the view layer of your MVC application.

2.17.1 Integrating Views with Controllers

Phalcon automatically passes the execution to the view component as soon as a particular controller has completed its cycle. The view component will look in the views folder for a folder named as the same name of the last controller executed and then for a file named as the last action executed. For instance, if a request is made to the URL `http://127.0.0.1/blog/posts/show/301`, Phalcon will parse the URL as follows:

Server Address	127.0.0.1
Phalcon Directory	blog
Controller	posts
Action	show
Parameter	301

The dispatcher will look for a “PostsController” and its action “showAction”. A simple controller file for this example:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function showAction($postId)
    {
        // Pass the $postId parameter to the view
        $this->view->setVar("postId", $postId);
    }
}
```

The setVar allows us to create view variables on demand so that they can be used in the view template. The example above demonstrates how to pass the \$postId parameter to the respective view template.

2.17.2 Hierarchical Rendering

Phalcon\Mvc\View supports a hierarchy of files and is the default component for view rendering in Phalcon. This hierarchy allows for common layout points (commonly used views), as well as controller named folders defining respective view templates.

This component uses by default PHP itself as the template engine, therefore views should have the .phtml extension. If the views directory is *app/views* then view component will find automatically for these 3 view files.

Name	File	Description
Action View	app/views/posts/show.phtml	This is the view related to the action. It only will be shown when the “show” action was executed.
Controller Layout	app/views/layouts/posts.phtml	This is the view related to the controller. It only will be shown for every action executed within the controller “posts”. All the code implemented in the layout will be reused for all the actions in this controller.
Main Layout	app/views/index.phtml	This is main action it will be shown for every controller or action executed within the application.

You are not required to implement all of the files mentioned above. Phalcon\Mvc\View will simply move to the next view level in the hierarchy of files. If all three view files are implemented, they will be processed as follows:

```
<!-- app/views/posts/show.phtml -->

<h3>This is show view!</h3>

<p>I have received the parameter <?php echo $postId ?></p>
```

```
<!-- app/views/layouts/posts.phtml -->

<h2>This is the "posts" controller layout!</h2>

<?php echo $this->getContent() ?>
```

```
<!-- app/views/index.phtml -->
<html>
    <head>
        <title>Example</title>
    </head>
    <body>

        <h1>This is main layout!</h1>

        <?php echo $this->getContent() ?>

    </body>
</html>
```

Note the lines where the method `$this->getContent()` was called. This method instructs Phalcon\Mvc\View on where to inject the contents of the previous view executed in the hierarchy. For the example above, the output will be:

The generated HTML by the request will be:

```
<!-- app/views/index.phtml -->
<html>
    <head>
```

```
<title>Example</title>
</head>
<body>

    <h1>This is main layout!</h1>

    <!-- app/views/layouts/posts.phtml -->

    <h2>This is the "posts" controller layout!</h2>

    <!-- app/views/posts/show.phtml -->

    <h3>This is show view!</h3>

    <p>I have received the parameter 101</p>

</body>
</html>
```

Using Templates

Templates are views that can be used to share common view code. They act as controller layouts, so you need to place them in the layouts directory.

```
<?php
```

```
use Phalcon\Mvc\Controller;

class PostsController extends Controller
{
    public function initialize()
    {
        $this->view->setTemplateAfter('common');
    }

    public function lastAction()
    {
        $this->flash->notice("These are the latest posts");
    }
}
```

```
<!-- app/views/index.phtml -->
<!DOCTYPE html>
<html>
    <head>
        <title>Blog's title</title>
    </head>
    <body>
        <?php echo $this->getContent() ?>
    </body>
</html>
```

```
<!-- app/views/layouts/common.phtml -->

<ul class="menu">
    <li><a href="/">Home</a></li>
    <li><a href="/articles">Articles</a></li>
    <li><a href="/contact">Contact us</a></li>
</ul>

<div class="content"><?php echo $this->getContent() ?></div>
```

```
<!-- app/views/layouts/posts.phtml -->

<h1>Blog Title</h1>

<?php echo $this->getContent() ?>
```

```
<!-- app/views/posts/last.phtml -->

<article>
    <h2>This is a title</h2>
    <p>This is the post content</p>
</article>

<article>
    <h2>This is another title</h2>
    <p>This is another post content</p>
</article>
```

The final output will be the following:

```
<!-- app/views/index.phtml -->
<!DOCTYPE html>
<html>
```

```

<head>
    <title>Blog's title</title>
</head>
<body>

    <!-- app/views/layouts/common.phtml -->

    <ul class="menu">
        <li><a href="/">Home</a></li>
        <li><a href="/articles">Articles</a></li>
        <li><a href="/contact">Contact us</a></li>
    </ul>

    <div class="content">

        <!-- app/views/layouts/posts.phtml -->

        <h1>Blog Title</h1>

        <!-- app/views/posts/last.phtml -->

        <article>
            <h2>This is a title</h2>
            <p>This is the post content</p>
        </article>

        <article>
            <h2>This is another title</h2>
            <p>This is another post content</p>
        </article>

    </div>

</body>
</html>

```

Control Rendering Levels

As seen above, `Phalcon\Mvc\View` supports a view hierarchy. You might need to control the level of rendering produced by the view component. The method `PhalconMvc\View::setRenderLevel()` offers this functionality.

This method can be invoked from the controller or from a superior view layer to interfere with the rendering process.

```

<?php

use Phalcon\Mvc\View;
use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function findAction()

```

```

{
    // This is an Ajax response so it doesn't generate any kind of view
    $this->view->setRenderLevel(View::LEVEL_NO_RENDER);

    //...
}

public function showAction($postId)
{
    // Shows only the view related to the action
    $this->view->setRenderLevel(View::LEVEL_ACTION_VIEW);
}

}

```

The available render levels are:

Class Constant	Description	Order
LEVEL_NO_RENDER	Indicates to avoid generating any kind of presentation.	
LEVEL_ACTION_VIEW	Generates the presentation to the view associated to the action.	1
LEVEL_BEFORE_TEMPLATE	Generates presentation templates prior to the controller layout.	2
LEVEL_LAYOUT	Generates the presentation to the controller layout.	3
LEVEL_AFTER_TEMPLATE	Generates the presentation to the templates after the controller layout.	4
LEVEL_MAIN_LAYOUT	Generates the presentation to the main layout. File views/index.phtml	5

Disabling render levels

You can permanently or temporarily disable render levels. A level could be permanently disabled if it isn't used at all in the whole application:

```

<?php

use Phalcon\Mvc\View;

$di->set('view', function() {

    $view = new View();

    //Disable several levels
    $view->disableLevel(array(
        View::LEVEL_LAYOUT => true,
        View::LEVEL_MAIN_LAYOUT => true
    ));

    return $view;
}, true);

```

Or disable temporarily in some part of the application:

```

<?php

use Phalcon\Mvc\View;

```

```
use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function findAction()
    {
        $this->view->disableLevel(View::LEVEL_MAIN_LAYOUT);
    }

}
```

Picking Views

As mentioned above, when `Phalcon\Mvc\View` is managed by `Phalcon\Mvc\Application` the view rendered is the one related with the last controller and action executed. You could override this by using the `Phalcon\Mvc\View::pick()` method:

```
<?php

use Phalcon\Mvc\Controller;

class ProductsController extends Controller
{

    public function listAction()
    {
        // Pick "views-dir/products/search" as view to render
        $this->view->pick("products/search");

        // Pick "views-dir/books/list" as view to render
        $this->view->pick(array('books'));

        // Pick "views-dir/products/search" as view to render
        $this->view->pick(array(1 => 'search'));
    }

}
```

Disabling the view

If your controller doesn't produce any output in the view (or not even have one) you may disable the view component avoiding unnecessary processing:

```
<?php

use Phalcon\Mvc\Controller;

class UsersController extends Controller
{

    public function closeSessionAction()
    {

}
```

```
{  
    //Close session  
    //...  
  
    //An HTTP Redirect  
    $this->response->redirect('index/index');  
  
    //Disable the view to avoid rendering  
    $this->view->disable();  
}  
  
}
```

You can return a ‘response’ object to avoid disable the view manually:

```
<?php  
  
use Phalcon\Mvc\Controller;  
  
class UsersController extends Controller  
{  
  
    public function closeSessionAction()  
    {  
        //Close session  
        //...  
  
        //An HTTP Redirect  
        return $this->response->redirect('index/index');  
    }  
  
}
```

2.17.3 Simple Rendering

`Phalcon\Mvc\View\Simple` is an alternative component to `Phalcon\Mvc\View`. It keeps most of the philosophy of `Phalcon\Mvc\View` but lacks of a hierarchy of files which is, in fact, the main feature of its counterpart.

This component allows the developer to have control of when a view is rendered and its location. In addition, this component can leverage of view inheritance available in template engines such as `Volt` and others.

The default component must be replaced in the service container:

```
<?php  
  
use Phalcon\Mvc\View\Simple as SimpleView;  
  
$di->set('view', function() {  
  
    $view = new SimpleView();  
  
    $view->setViewsDir('../app/views/');  
  
    return $view;  
}, true);
```

Automatic rendering must be disabled in `Phalcon\Mvc\Application` (if needed):

```
<?php

use Phalcon\Mvc\Application;

try {

    $application = new Application($di);

    $application->useImplicitView(false);

    echo $application->handle()->getContent();

} catch (\Exception $e) {
    echo $e->getMessage();
}
```

To render a view it's necessary to call the render method explicitly indicating the relative path to the view you want to display:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends \Controller
{

    public function indexAction()
    {
        //Render 'views-dir/index.phtml'
        echo $this->view->render('index');

        //Render 'views-dir/posts/show.phtml'
        echo $this->view->render('posts/show');

        //Render 'views-dir/index.phtml' passing variables
        echo $this->view->render('index', array('posts' => Posts::find()));

        //Render 'views-dir/posts/show.phtml' passing variables
        echo $this->view->render('posts/show', array('posts' => Posts::find()));
    }
}
```

2.17.4 Using Partials

Partial templates are another way of breaking the rendering process into simpler more manageable chunks that can be reused by different parts of the application. With a partial, you can move the code for rendering a particular piece of a response to its own file.

One way to use partials is to treat them as the equivalent of subroutines: as a way to move details out of a view so that your code can be more easily understood. For example, you might have a view that looks like this:

```
<div class="top"><?php $this->partial("shared/ad_banner") ?></div>

<div class="content">
    <h1>Robots</h1>
```

```
<p>Check out our specials for robots:</p>
...
</div>

<div class="footer"><?php $this->partial("shared/footer") ?></div>
```

Method partial() does accept a second parameter as an array of variables/parameters that only will exists in the scope of the partial:

```
<?php $this->partial("shared/ad_banner", array('id' => $site->id, 'size' => 'big')) ?>
```

2.17.5 Transfer values from the controller to views

Phalcon\Mvc\View is available in each controller using the view variable (\$this->view). You can use that object to set variables directly to the view from a controller action by using the setVar() method.

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function showAction()
    {
        //Pass all the posts to the views
        $this->view->setVar("posts", Posts::find());

        //Using the magic setter
        $this->view->posts = Posts::find();

        //Passing more than one variable at the same time
        $this->view->setVars(array(
            'title' => $post->title,
            'content' => $post->content
        ));
    }
}
```

A variable with the name of the first parameter of setVar() will be created in the view, ready to be used. The variable can be of any type, from a simple string, integer etc. variable to a more complex structure such as array, collection etc.

```
<div class="post">
<?php

foreach ($posts as $post) {
    echo "<h1>", $post->title, "</h1>";
}

?>
</div>
```

2.17.6 Using models in the view layer

Application models are always available at the view layer. The `Phalcon\Loader` will instantiate them at runtime automatically:

```
<div class="categories">
<?php

    foreach (Categories::find("status = 1") as $category) {
        echo "<span class='category'>", $category->name, "</span>";
    }

?>
</div>
```

Although you may perform model manipulation operations such as `insert()` or `update()` in the view layer, it is not recommended since it is not possible to forward the execution flow to another controller in the case of an error or an exception.

2.17.7 Caching View Fragments

Sometimes when you develop dynamic websites and some areas of them are not updated very often, the output is exactly the same between requests. `Phalcon\Mvc\View` offers caching a part or the whole rendered output to increase performance.

`Phalcon\Mvc\View` integrates with `Phalcon\Cache` to provide an easier way to cache output fragments. You could manually set the cache handler or set a global handler:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function showAction()
    {
        //Cache the view using the default settings
        $this->view->cache(true);
    }

    public function showArticleAction()
    {
        // Cache this view for 1 hour
        $this->view->cache(array(
            "lifetime" => 3600
        ));
    }

    public function resumeAction()
    {
        //Cache this view for 1 day with the key "resume-cache"
        $this->view->cache(
            array(
                "lifetime" => 86400,
                "key"      => "resume-cache",
            )
        );
    }
}
```

```
    );
}

public function downloadAction()
{
    //Passing a custom service
    $this->view->cache(
        array(
            "service"  => "myCache",
            "lifetime" => 86400,
            "key"       => "resume-cache",
        )
    );
}

}
```

When we do not define a key to the cache, the component automatically creates one using a `md5` hash of the name of the view currently being rendered. It is a good practice to define a key for each action so you can easily identify the cache associated with each view.

When the View component needs to cache something it will request a cache service from the services container. The service name convention for this service is “viewCache”:

```
<?php

use Phalcon\Cache\Frontend\Output as OutputFrontend;
use Phalcon\Cache\Backend\Memcache as MemcacheBackend;

//Set the views cache service
$di->set('viewCache', function() {

    //Cache data for one day by default
    $frontCache = new OutputFrontend(array(
        "lifetime" => 86400
    ));

    //Memcached connection settings
    $cache = new MemcacheBackend($frontCache, array(
        "host" => "localhost",
        "port" => "11211"
    ));

    return $cache;
});
```

The frontend must always be `Phalcon\Cache\Frontend\Output` and the service ‘viewCache’ must be registered as always open (not shared) in the services container (DI)

When using views, caching can be used to prevent controllers from needing to generate view data on each request.

To achieve this we must identify uniquely each cache with a key. First we verify that the cache does not exist or has expired to make the calculations/queries to display data in the view:

```
<?php

use Phalcon\Mvc\Controller;

class DownloadController extends Controller
{
```

```

public function indexAction()
{
    //Check whether the cache with key "downloads" exists or has expired
    if ($this->view->getCache()->exists('downloads')) {

        //Query the latest downloads
        $latest = Downloads::find(array(
            'order' => 'created_at DESC'
        ));

        $this->view->latest = $latest;
    }

    //Enable the cache with the same key "downloads"
    $this->view->cache(array(
        'key' => 'downloads'
    ));
}
}
}

```

The PHP alternative site is an example of implementing the caching of fragments.

2.17.8 Template Engines

Template Engines help designers to create views without the use of a complicated syntax. Phalcon includes a powerful and fast templating engine called [Volt](#).

Additionally, [Phalcon\Mvc\View](#) allows you to use other template engines instead of plain PHP or Volt.

Using a different template engine, usually requires complex text parsing using external PHP libraries in order to generate the final output for the user. This usually increases the number of resources that your application will use.

If an external template engine is used, [Phalcon\Mvc\View](#) provides exactly the same view hierarchy and it's still possible to access the API inside these templates with a little more effort.

This component uses adapters, these help Phalcon to speak with those external template engines in a unified way, let's see how to do that integration.

Creating your own Template Engine Adapter

There are many template engines, which you might want to integrate or create one of your own. The first step to start using an external template engine is create an adapter for it.

A template engine adapter is a class that acts as bridge between [Phalcon\Mvc\View](#) and the template engine itself. Usually it only needs two methods implemented: `__construct()` and `render()`. The first one receives the [Phalcon\Mvc\View](#) instance that creates the engine adapter and the DI container used by the application.

The method `render()` accepts an absolute path to the view file and the view parameters set using `$this->view->setVar()`. You could read or require it when it's necessary.

```

<?php

use Phalcon\Mvc\Engine;

class MyTemplateAdapter extends Engine

```

```
{

    /**
     * Adapter constructor
     *
     * @param \Phalcon\Mvc\View $view
     * @param \Phalcon\DI $di
     */
    public function __construct($view, $di)
    {
        //Initialize here the adapter
        parent::__construct($view, $di);
    }

    /**
     * Renders a view using the template engine
     *
     * @param string $path
     * @param array $params
     */
    public function render($path, $params)
    {

        // Access view
        $view = $this->_view;

        // Access options
        $options = $this->_options;

        //Render the view
        //...
    }
}
```

Changing the Template Engine

You can replace or add more a template engine from the controller as follows:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {
        // Set the engine
        $this->view->registerEngines(
            array(
                ".my-html" => "MyTemplateAdapter"
            )
        );
    }

    public function showAction()
```

```

{
    // Using more than one template engine
    $this->view->registerEngines(
        array(
            ".my-html" => 'MyTemplateAdapter',
            ".phtml"    => 'Phalcon\Mvc\View\Engine\Php'
        )
    );
}

}

```

You can replace the template engine completely or use more than one template engine at the same time. The method `Phalcon\Mvc\View::registerEngines()` accepts an array containing data that define the template engines. The key of each engine is an extension that aids in distinguishing one from another. Template files related to the particular engine must have those extensions.

The order that the template engines are defined with `Phalcon\Mvc\View::registerEngines()` defines the relevance of execution. If `Phalcon\Mvc\View` finds two views with the same name but different extensions, it will only render the first one.

If you want to register a template engine or a set of them for each request in the application. You could register it when the view service is created:

```

<?php

use Phalcon\Mvc\View;

//Setting up the view component
$di->set('view', function() {

    $view = new View();

    //A trailing directory separator is required
    $view->setViewsDir('../app/views/');

    $view->registerEngines(array(
        ".my-html" => 'MyTemplateAdapter'
    ));

    return $view;
}, true);

```

There are adapters available for several template engines on the [Phalcon Incubator](#)

2.17.9 Injecting services in View

Every view executed is included inside a `Phalcon\DI\Injectable` instance, providing easy access to the application's service container.

The following example shows how to write a jQuery `ajax` request using a url with the framework conventions. The service "url" (usually `Phalcon\Mvc\Url`) is injected in the view by accessing a property with the same name:

```

<script type="text/javascript">

$.ajax({
    url: "<?php echo $this->url->get("cities/get") ?>"

```

```
})
.done(function() {
    alert("Done!");
});

</script>
```

2.17.10 Stand-Alone Component

All the components in Phalcon can be used as *glue* components individually because they are loosely coupled to each other:

Hierarchical Rendering

Using `Phalcon\Mvc\View` in a stand-alone mode can be demonstrated below

```
<?php

use Phalcon\Mvc\View;

$view = new View();

//A trailing directory separator is required
$view->setViewsDir("../app/views/");

// Passing variables to the views, these will be created as local variables
$view->setVar("someProducts", $products);
$view->setVar("someFeatureEnabled", true);

//Start the output buffering
$view->start();

//Render all the view hierarchy related to the view products/list.phtml
$view->render("products", "list");

//Finish the output buffering
$view->finish();

echo $view->getContent();
```

A short syntax is also available:

```
<?php

use Phalcon\Mvc\View;

$view = new View();

echo $view->getRender('products', 'list',
    array(
        "someProducts"      => $products,
        "someFeatureEnabled" => true
    ),
    function($view) {
        //Set any extra options here
        $view->setViewsDir("../app/views/");
    }
);
```

```

        $view->setRenderLevel(View::LEVEL_LAYOUT);
    }
);

```

Simple Rendering

Using `Phalcon\Mvc\View\Simple` in a stand-alone mode can be demonstrated below:

```

<?php

use Phalcon\Mvc\View\Simple as SimpleView;

$view = new SimpleView();

//A trailing directory separator is required
$view->setViewsDir("../app/views/");

// Render a view and return its contents as a string
echo $view->render("templates/welcomeMail");

// Render a view passing parameters
echo $view->render("templates/welcomeMail", array(
    'email' => $email,
    'content' => $content
));

```

2.17.11 View Events

`Phalcon\Mvc\View` and `Phalcon\Mvc\View\Simple` are able to send events to an `EventsManager` if it is present. Events are triggered using the type “view”. Some events when returning boolean false could stop the active operation. The following events are supported:

Event Name	Triggered	Can stop operation?
beforeRender	Triggered before starting the render process	Yes
beforeRenderView	Triggered before rendering an existing view	Yes
afterRenderView	Triggered after rendering an existing view	No
afterRender	Triggered after completing the render process	No
notFoundView	Triggered when a view was not found	No

The following example demonstrates how to attach listeners to this component:

```

<?php

use Phalcon\Mvc\View;
use Phalcon\Events\Manager as EventsManager;

$di->set('view', function() {

    //Create an events manager
    $eventsManager = new EventsManager();

    //Attach a listener for type "view"
    $eventsManager->attach("view", function($event, $view) {
        echo $event->getType(), ' - ', $view->getActiveRenderPath(), PHP_EOL;
    });
});

```

```
$view = new View();
$view->setViewsDir("../app/views/");

//Bind the eventsManager to the view component
$view->setEventsManager($eventsManager);

return $view;

}, true);
```

The following example shows how to create a plugin that clean/repair the HTML produced by the render process using Tidy:

```
<?php

class TidyPlugin
{

    public function afterRender($event, $view)
    {

        $tidyConfig = array(
            'clean'          => true,
            'output-xhtml'   => true,
            'show-body-only' => true,
            'wrap'           => 0,
        );

        $tidy = tidy_parse_string($view->getContent(), $tidyConfig, 'UTF8');
        $tidy->cleanRepair();

        $view->setContent((string) $tidy);
    }
}

//Attach the plugin as a listener
$eventsManager->attach("view:afterRender", new TidyPlugin());
```

2.18 View Helpers

Writing and maintaining HTML markup can quickly become a tedious task because of the naming conventions and numerous attributes that have to be taken into consideration. Phalcon deals with this complexity by offering [Phalcon\Tag](#), which in turn offers view helpers to generate HTML markup.

This component can be used in a plain HTML+PHP view or in a [Volt](#) template.

This guide is not intended to be a complete documentation of available helpers and their arguments. Please visit the [Phalcon\Tag](#) page in the API for a complete reference.

2.18.1 Document Type of Content

Phalcon provides `Phalcon\Tag::setDoctype()` helper to set document type of the content. Document type setting may affect HTML output produced by other tag helpers. For example, if you set XHTML document type family, helpers that return or output HTML tags will produce self-closing tags to follow valid XHTML standard.

Available document type constants in Phalcon\Tag namespace are:

Constant	Document type
HTML32	HTML 3.2
HTML401_STRICT	HTML 4.01 Strict
HTML401_TRANSITIONAL	HTML 4.01 Transitional
HTML401_FRAMESET	HTML 4.01 Frameset
HTML5	HTML 5
XHTML10_STRICT	XHTML 1.0 Strict
XHTML10_TRANSITIONAL	XHTML 1.0 Transitional
XHTML10_FRAMESET	XHTML 1.0 Frameset
XHTML11	XHTML 1.1
XHTML20	XHTML 2.0
XHTML5	XHTML 5

Setting document type.

```
<?php

use Phalcon\Tag;

$this->tag->setDoctype(Tag::HTML401_STRICT);
?>
```

Getting document type.

```
<?= $this->tag->getDoctype() ?>
<html>
<!-- your HTML code -->
</html>
```

The following HTML will be produced.

```
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01//EN"
          "http://www.w3.org/TR/html4/strict.dtd">
<html>
<!-- your HTML code -->
</html>
```

Volt syntax:

```
{{ get_doctype() }}
<html>
<!-- your HTML code -->
</html>
```

2.18.2 Generating Links

A real common task in any web application or website is to produce links that allow us to navigate from one page to another. When they are internal URLs we can create them in the following manner:

```
<!-- for the default route -->
<?= $this->tag->linkTo("products/search", "Search") ?>

<!-- with CSS attributes -->
<?= $this->tag->linkTo(array('products/edit/10', 'Edit', 'class' => 'edit-btn')) ?>
```

```
<!-- for a named route -->
<?= $this->tag->linkTo(array(array('for' => 'show-product', 'title' => 123, 'name' => 'carrots'), 'Sh
```

Actually, all produced URLs are generated by the component `Phalcon\Mvc\Url` (or service “url” failing)

Same links generated with Volt:

```
<!-- for the default route -->
{{ link_to("products/search", "Search") }}

<!-- for a named route -->
{{ link_to(['for': 'show-product', 'id': 123, 'name': 'carrots'], 'Show') }}

<!-- for a named route with class -->
{{ link_to(['for': 'show-product', 'id': 123, 'name': 'carrots'], 'Show', 'class'=>'edit-btn') }}
```

2.18.3 Creating Forms

Forms in web applications play an essential part in retrieving user input. The following example shows how to implement a simple search form using view helpers:

```
<!-- Sending the form by method POST -->
<?= $this->tag->form("products/search") ?>
    <label for="q">Search:</label>
    <?= $this->tag->textField("q") ?>
    <?= $this->tag->submitButton("Search") ?>
<?= $this->tag->endForm() ?>

<!-- Specifying another method or attributes for the FORM tag -->
<?= $this->tag->form(array("products/search", "method" => "get")); ?>
    <label for="q">Search:</label>
    <?= $this->tag->textField("q"); ?>
    <?= $this->tag->submitButton("Search"); ?>
<?= $this->tag->endForm() ?>
```

This last code will generate the following HTML:

```
<form action="/store/products/search/" method="get">
    <label for="q">Search:</label>
    <input type="text" id="q" value="" name="q" />
    <input type="submit" value="Search" />
</form>
```

Same form generated in Volt:

```
<!-- Specifying another method or attributes for the FORM tag -->
{{ form("products/search", "method": "get") }}
    <label for="q">Search:</label>
    {{ text_field("q") }}
    {{ submit_button("Search") }}
{{ endform() }}
```

Phalcon also provides a form builder to create forms in an object-oriented manner.

2.18.4 Helpers to Generate Form Elements

Phalcon provides a series of helpers to generate form elements such as text fields, buttons and more. The first parameter of each helper is always the name of the element to be generated. When the form is submitted, the name will be passed along with the form data. In a controller you can get these values using the same name by using the `getPost()` and `getQuery()` methods on the request object (`$this->request`).

```
<?php echo $this->tag->textField("username") ?>

<?php echo $this->tag->textArea(array(
    "comment",
    "This is the content of the text-area",
    "cols" => "6",
    "rows" => 20
)) ?>

<?php echo $this->tag->passwordField(array(
    "password",
    "size" => 30
)) ?>

<?php echo $this->tag->hiddenField(array(
    "parent_id",
    "value"=> "5"
)) ?>
```

Volt syntax:

```
{{ text_field("username") }}

{{ text_area("comment", "This is the content", "cols": "6", "rows": 20) }}

{{ password_field("password", "size": 30) }}

{{ hidden_field("parent_id", "value": "5") }}
```

2.18.5 Making Select Boxes

Generating select boxes (select box) is easy, especially if the related data is stored in PHP associative arrays. The helpers for select elements are `Phalcon\Tag::select()` and `Phalcon\Tag::selectStatic()`. `Phalcon\Tag::select()` has been specifically designed to work with `Phalcon\Mvc\Model`, while `Phalcon\Tag::selectStatic()` can work with PHP arrays.

```
<?php

// Using data from a resultset
echo $this->tag->select(
    array(
        "productId",
        Products::find("type = 'vegetables'"),
        "using" => array("id", "name")
    )
);

// Using data from an array
echo $this->tag->selectStatic(
    array(
        "status",
        "value"
    )
);
```

```

        array(
            "A" => "Active",
            "I" => "Inactive",
        )
    );
);

```

The following HTML will generated:

```

<select id="productId" name="productId">
    <option value="101">Tomato</option>
    <option value="102">Lettuce</option>
    <option value="103">Beans</option>
</select>

<select id="status" name="status">
    <option value="A">Active</option>
    <option value="I">Inactive</option>
</select>

```

You can add an “empty” option to the generated HTML:

```

<?php

// Creating a Select Tag with an empty option
echo $this->tag->select(
    array(
        "productId",
        Products::find("type = 'vegetables'"),
        "using" => array("id", "name"),
        "useEmpty" => true
    )
);

```

```

<select id="productId" name="productId">
    <option value="">Choose..</option>
    <option value="101">Tomato</option>
    <option value="102">Lettuce</option>
    <option value="103">Beans</option>
</select>

```

```

<?php

// Creating a Select Tag with an empty option with default text
echo $this->tag->select(
    array(
        'productId',
        Products::find("type = 'vegetables'"),
        'using'      => array('id', "name"),
        'useEmpty'   => true,
        'emptyText'  => 'Please, choose one...',
        'emptyValue' => '@'
    )
);

```

```

<select id="productId" name="productId">
    <option value="@">Please, choose one..</option>
    <option value="101">Tomato</option>
    <option value="102">Lettuce</option>

```

```
<option value="103">Beans</option>
</select>
```

Volt syntax for above example:

```
{# Creating a Select Tag with an empty option with default text #}
{{ select('productId', products, 'using': ['id', 'name'],
    'useEmpty': true, 'emptyText': 'Please, choose one...', 'emptyValue': '@') }}
```

2.18.6 Assigning HTML attributes

All the helpers accept an array as their first parameter which can contain additional HTML attributes for the element generated.

```
<?php $this->tag->textField(
    array(
        "price",
        "size"      => 20,
        "maxlength" => 30,
        "placeholder" => "Enter a price",
    )
) ?>
```

or using Volt:

```
{{ text_field("price", "size": 20, "maxlength": 30, "placeholder": "Enter a price") }}
```

The following HTML is generated:

```
<input type="text" name="price" id="price" size="20" maxlength="30"
    placeholder="Enter a price" />
```

2.18.7 Setting Helper Values

From Controllers

It is a good programming principle for MVC frameworks to set specific values for form elements in the view. You can set those values directly from the controller using Phalcon\Tag::setDefault(). This helper preloads a value for any helpers present in the view. If any helper in the view has a name that matches the preloaded value, it will use it, unless a value is directly assigned on the helper in the view.

```
<?php

use Phalcon\Mvc\Controller;

class ProductsController extends Controller
{

    public function indexAction()
    {
        $this->tag->setDefault("color", "Blue");
    }

}
```

At the view, a selectStatic helper matches the same index used to preset the value. In this case “color”:

```
<?php

echo $this->tag->selectStatic(
    array(
        "color",
        array(
            "Yellow" => "Yellow",
            "Blue"    => "Blue",
            "Red"     => "Red"
        )
    )
);
```

This will generate the following select tag with the value “Blue” selected:

```
<select id="color" name="color">
    <option value="Yellow">Yellow</option>
    <option value="Blue" selected="selected">Blue</option>
    <option value="Red">Red</option>
</select>
```

From the Request

A special feature that the Phalcon\Tag helpers have is that they keep the values of form helpers between requests. This way you can easily show validation messages without losing entered data.

Specifying values directly

Every form helper supports the parameter “value”. With it you can specify a value for the helper directly. When this parameter is present, any preset value using setDefault() or via request will be ignored.

2.18.8 Changing dynamically the Document Title

Phalcon\Tag offers helpers to change dynamically the document title from the controller. The following example demonstrates just that:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function initialize()
    {
        $this->tag->setTitle("Your Website");
    }

    public function indexAction()
    {
        $this->tag->prependTitle("Index of Posts - ");
    }

}
```

```
<html>
    <head>
        <?php echo $this->tag->getTitle(); ?>
    </head>
    <body>

    </body>
</html>
```

The following HTML will generated:

```
<html>
    <head>
        <title>Index of Posts - Your Website</title>
    </head>
    <body>

    </body>
</html>
```

2.18.9 Static Content Helpers

Phalcon\Tag also provide helpers to generate tags such as script, link or img. They aid in quick and easy generation of the static resources of your application

Images

```
<?php

// Generate 
echo $this->tag->image("img/hello.gif");

// Generate 
echo $this->tag->image(
    array(
        "img/hello.gif",
        "alt" => "alternative text"
    )
);
```

Volt syntax:

```
{# Generate  #-}
{{ image("img/hello.gif") }}

{# Generate  #-}
{{ image("img/hello.gif", "alt": "alternative text") }}
```

Stylesheets

```
<?php

// Generate <link rel="stylesheet" href="http://fonts.googleapis.com/css?family=Rosario" type="text/css">
echo $this->tag->stylesheetLink("http://fonts.googleapis.com/css?family=Rosario", false);
```

```
// Generate <link rel="stylesheet" href="/your-app/css/styles.css" type="text/css">
echo $this->tag->stylesheetLink("css/styles.css");
```

Volt syntax:

```
{# Generate <link rel="stylesheet" href="http://fonts.googleapis.com/css?family=Rosario" type="text/css">
{{ stylesheet_link("http://fonts.googleapis.com/css?family=Rosario", false) }}

{# Generate <link rel="stylesheet" href="/your-app/css/styles.css" type="text/css"> #}
{{ stylesheet_link("css/styles.css") }}
```

Javascript

```
<?php

// Generate <script src="http://localhost/javascript/jquery.min.js" type="text/javascript"></script>
echo $this->tag->javascriptInclude("http://localhost/javascript/jquery.min.js", false);

// Generate <script src="/your-app/javascript/jquery.min.js" type="text/javascript"></script>
echo $this->tag->javascriptInclude("javascript/jquery.min.js");
```

Volt syntax:

```
{# Generate <script src="http://localhost/javascript/jquery.min.js" type="text/javascript"></script>
{{ javascript_include("http://localhost/javascript/jquery.min.js", false) }}

{# Generate <script src="/your-app/javascript/jquery.min.js" type="text/javascript"></script> #}
{{ javascript_include("javascript/jquery.min.js") }}
```

HTML5 elements - generic HTML helper

Phalcon offers a generic HTML helper that allows the generation of any kind of HTML element. It is up to the developer to produce a valid HTML element name to the helper.

```
<?php

// Generate
// <canvas id="canvas1" width="300" class="cnvclass">
// This is my canvas
// </canvas>
echo $this->tag->tagHtml("canvas", array("id" => "canvas1", "width" => "300", "class" => "cnvclass"));
echo "This is my canvas";
echo $this->tag->tagHtmlClose("canvas");
```

Volt syntax:

```
{# Generate
<canvas id="canvas1" width="300" class="cnvclass">
This is my canvas
</canvas> #}
{{ tag_html("canvas", ["id": "canvas1", "width": "300", "class": "cnvclass"], false, true, true) }}
    This is my canvas
{{ tag_html_close("canvas") }}
```

2.18.10 Tag Service

Phalcon\Tag is available via the ‘tag’ service, this means you can access it from any part of the application where the services container is located:

```
<?php echo $this->tag->linkTo('pages/about', 'About') ?>
```

You can easily add new helpers to a custom component replacing the service ‘tag’ in the services container:

```
<?php

use Phalcon\Tag;

class MyTags extends Tag
{
    //...

    //Create a new helper
    static public function myAmazingHelper($parameters)
    {
        //...
    }

    //Override an existing method
    static public function textField($parameters)
    {
        //...
    }
}
```

Then change the definition of the service ‘tag’:

```
<?php

$di['tag'] = function() {
    return new MyTags();
};
```

2.18.11 Creating your own helpers

You can easily create your own helpers. First, start by creating a new folder within the same directory as your controllers and models. Give it a title that is relative to what you are creating. For our example here, we can call it “customhelpers”. Next we will create a new file titled MyTags.php within this new directory. At this point, we have a structure that looks similar to : /app/customhelpers/MyTags.php. In MyTags.php, we will extend the Phalcon\Tag and implement your own helper. Below is a simple example of a custom helper:

```
<?php

use Phalcon\Tag;

class MyTags extends Tag
{

    /**
     * Generates a widget to show a HTML5 audio tag
     *
     * @param array

```

```
* @return string
*/
static public function audioField($parameters)
{

    // Converting parameters to array if it is not
    if (!is_array($parameters)) {
        $parameters = array($parameters);
    }

    // Determining attributes "id" and "name"
    if (!isset($parameters[0])) {
        $parameters[0] = $parameters["id"];
    }

    $id = $parameters[0];
    if (!isset($parameters["name"])) {
        $parameters["name"] = $id;
    } else {
        if (!$parameters["name"]) {
            $parameters["name"] = $id;
        }
    }

    // Determining widget value,
    // \Phalcon\Tag::setDefault() allows to set the widget value
    if (isset($parameters["value"])) {
        $value = $parameters["value"];
        unset($parameters["value"]);
    } else {
        $value = self::getValue($id);
    }

    // Generate the tag code
    $code = '<audio id="'.$id.'" value="'.$value.'" ';
    foreach ($parameters as $key => $attributeValue) {
        if (!is_integer($key)) {
            $code .= $key. '=' .$attributeValue. ' ';
        }
    }
    $code .= " />";

    return $code;
}

}
```

After creating our custom helper, we will autoload the new directory that contains our helper class from our “index.php” located in the public directory.

```
<?php

use Phalcon\Loader;
use Phalcon\Mvc\Application;
use Phalcon\DI\FactoryDefault();
use Phalcon\Exception as PhalconException;

try {
```

```

$loader = new Loader();
$loader->registerDirs(array(
    '../app/controllers',
    '../app/models',
    '../app/customhelpers' // Add the new helpers folder
))->register();

$di = new FactoryDefault();

// Assign our new tag a definition so we can call it
$di->set('MyTags', function()
{
    return new MyTags();
});

$application = new Application($di);
echo $application->handle()->getContent();

} catch(PhalconException $e) {
    echo "PhalconException: ", $e->getMessage();
}

}

```

Now you are ready to use your new helper within your views:

```

<body>

<?php

echo MyTags::audioField(array(
    'name' => 'test',
    'id'   => 'audio_test',
    'src'  => '/path/to/audio.mp3'
));
?>

</body>

```

In next chapter, we'll talk about [Volt](#) a faster template engine for PHP, where you can use a more friendly syntax for using helpers provided by PhalconTag.

2.19 Assets Management

Phalcon\Assets is a component that allows the developer to manage static resources such as css stylesheets or javascript libraries in a web application.

Phalcon\Assets\Manager is available in the services container, so you can add resources from any part of the application where the container is available.

2.19.1 Adding Resources

Assets supports two built-in resources: css and javascripts. You can create other resources if you need. The assets manager internally stores two default collections of resources one for javascript and another for css.

You can easily add resources to these collections like follows:

```
<?php

use Phalcon\Mvc\Controller;

class IndexController extends Controller
{
    public function index()
    {

        // Add some local CSS resources
        $this->assets
            ->addCss('css/style.css')
            ->addCss('css/index.css');

        // and some local javascript resources
        $this->assets
            ->addJs('js/jquery.js')
            ->addJs('js/bootstrap.min.js');

    }
}
```

Then in the views added resources can be printed:

```
<html>
    <head>
        <title>Some amazing website</title>
        <?php $this->assets->outputCss() ?>
    </head>
    <body>

        <!-- ... -->

        <?php $this->assets->outputJs() ?>
    </body>
<html>
```

Volt syntax:

```
<html>
    <head>
        <title>Some amazing website</title>
        {{ assets.outputCss() }}
    </head>
    <body>

        <!-- ... -->

        {{ assets.outputJs() }}
    </body>
<html>
```

2.19.2 Local/Remote resources

Local resources are those who're provided by the same application and they're located in the document root of the application. URLs in local resources are generated by the 'url' service, usually `Phalcon\Mvc\Url`.

Remote resources are those such as common library like jquery, bootstrap, etc. that are provided by a CDN.

```
<?php

public function indexAction()
{
    // Add some local CSS resources
    $this->assets
        ->addCss('://netdna.bootstrapcdn.com/twitter-bootstrap/2.3.1/css/bootstrap-combined.min.css',
                  'css/style.css', true);
}
```

2.19.3 Collections

Collections groups resources of the same type, the assets manager implicitly creates two collections: css and js. You can create additional collections to group specific resources for ease of placing those resources in the views:

```
<?php

//Javascripts in the header
$this->assets
    ->collection('header')
    ->addJs('js/jquery.js')
    ->addJs('js/bootstrap.min.js');

//Javascripts in the footer
$this->assets
    ->collection('footer')
    ->addJs('js/jquery.js')
    ->addJs('js/bootstrap.min.js');
```

Then in the views:

```
<html>
    <head>
        <title>Some amazing website</title>
        <?php $this->assets->outputJs('header') ?>
    </head>
    <body>

        <!-- ... -->

        <?php $this->assets->outputJs('footer') ?>
    </body>
<html>
```

Volt syntax:

```
<html>
    <head>
        <title>Some amazing website</title>
        {{ assets.outputCss('header') }}
    </head>
    <body>

        <!-- ... -->
```

```
    {{ assets.outputJs('footer') }}
```

```
</body>
<html>
```

2.19.4 Prefixes

Collections can be URL-prefixed, this allows to easily change from a server to other at any moment:

```
<?php

$scripts = $this->assets->collection('footer');

if ($config->environment == 'development') {
    $scripts->setPrefix('/');
} else {
    $scripts->setPrefix('http://cdn.example.com/');
}

$scripts->addJs('js/jquery.js')
    ->addJs('js/bootstrap.min.js');
```

A chainable syntax is available too:

```
<?php

$scripts = $assets
    ->collection('header')
    ->setPrefix('http://cdn.example.com/')
    ->setLocal(false)
    ->addJs('js/jquery.js')
    ->addJs('js/bootstrap.min.js');
```

2.19.5 Minification/Filtering

Phalcon\Assets provides built-in minification of Javascript and CSS resources. The developer can create a collection of resources instructing the Assets Manager which ones must be filtered and which ones must be left as they are. In addition to the above, Jsmin by Douglas Crockford is part of the core extension offering minification of javascript files for maximum performance. In the CSS land, CSSMin by Ryan Day is also available to minify CSS files:

The following example shows how to minify a collection of resources:

```
<?php

$manager

// These Javascripts are located in the page's bottom
->collection('jsFooter')

// The name of the final output
->setTargetPath('final.js')

// The script tag is generated with this URI
->setTargetUri('production/final.js')

// This is a remote resource that does not need filtering
->addJs('code.jquery.com/jquery-1.10.0.min.js', false, false)
```

```
// These are local resources that must be filtered
->addJs('common-functions.js')
->addJs('page-functions.js')

// Join all the resources in a single file
->join(true)

// Use the built-in Jsmin filter
->addFilter(new Phalcon\Assets\Filters\Jsmin())

// Use a custom filter
->addFilter(new MyApp\Assets\Filters\LicenseStamper());
```

It starts getting a collection of resources from the assets manager, a collection can contain javascript or css resources but not both. Some resources may be remote, that is, they're obtained by HTTP from a remote source for further filtering. It is recommended to convert the external resources to local eliminating the overhead of obtaining them.

```
<?php

// These Javascripts are located in the page's bottom
$js = $manager->collection('jsFooter');
```

As seen above, method addJs is used to add resources to the collection, the second parameter indicates whether the resource is external or not and the third parameter indicates whether the resource should be filtered or left as is:

```
<?php

// This a remote resource that does not need filtering
$js->addJs('code.jquery.com/jquery-1.10.0.min.js', false, false);

// These are local resources that must be filtered
$js->addJs('common-functions.js');
$js->addJs('page-functions.js');
```

Filters are registered in the collection, multiple filters are allowed, content in resources are filtered in the same order as filters were registered:

```
<?php

//Use the built-in Jsmin filter
$js->addFilter(new Phalcon\Assets\Filters\Jsmin());

//Use a custom filter
$js->addFilter(new MyApp\Assets\Filters\LicenseStamper());
```

Note that both built-in and custom filters can be transparently applied to collections. Last step is decide if all the resources in the collection must be joined in a single file or serve each of them individually. To tell the collection that all resources must be joined you can use the method 'join':

```
<?php

// This a remote resource that does not need filtering
$js->join(true);

//The name of the final file path
$js->setTargetPath('public/production/final.js');

//The script html tag is generated with this URI
$js->setTargetUri('production/final.js');
```

If resources are going to be joined, we need also to define which file will be used to store the resources and which uri will be used to show it. These settings are set up with `setTargetPath()` and `setTargetUri()`.

Built-In Filters

Phalcon provides 2 built-in filters to minify both javascript and css respectively, their C-backend provide the minimum overhead to perform this task:

Filter	Description
Phalcon\Assets\Filters\Jsmin	Minifies Javascript removing unnecessary characters that are ignored by Javascript interpreters/compilers
Phalcon\Assets\Filters\Cssmin	Minifies CSS removing unnecessary characters that are already ignored by browsers

Custom Filters

In addition to built-in filters, a developer can create his own filters. These can take advantage of existing and more advanced tools like [YUI](#), [Sass](#), [Closure](#), etc.:

```
<?php

use Phalcon\Assets\FilterInterface;

/**
 * Filters CSS content using YUI
 *
 * @param string $contents
 * @return string
 */
class CssYUICompressor implements FilterInterface
{

    protected $_options;

    /**
     * CssYUICompressor constructor
     *
     * @param array $options
     */
    public function __construct($options)
    {
        $this->_options = $options;
    }

    /**
     * Do the filtering
     *
     * @param string $contents
     * @return string
     */
    public function filter($contents)
    {

        //Write the string contents into a temporal file
    }
}
```

```

file_put_contents('temp/my-temp-1.css', $contents);

system(
    $this->_options['java-bin'] .
    '-jar ' .
    $this->_options['yui'] .
    '--type css ' .
    'temp/my-temp-file-1.css ' .
    $this->_options['extra-options'] .
    '-o temp/my-temp-file-2.css'
);

//Return the contents of file
return file_get_contents("temp/my-temp-file-2.css");
}
}

```

Usage:

```

<?php

// Get some CSS collection
$css = $this->assets->get('head');

// Add/Enable the YUI compressor filter in the collection
$css->addFilter(new CssYUICompressor(array(
    'java-bin'      => '/usr/local/bin/java',
    'yui'           => '/some/path/yuicompressor-x.y.z.jar',
    'extra-options' => '--charset utf8'
)));

```

2.19.6 Custom Output

Methods `outputJs` and `outputCss` are available to generate the necessary HTML code according to each type of resources. You can override this method or print the resources manually in the following way:

```

<?php

use Phalcon\Tag;

foreach ($this->assets->collection('js') as $resource) {
    echo Tag:::javascriptInclude($resource->getPath());
}

```

2.20 Volt: Template Engine

Volt is an ultra-fast and designer friendly templating language written in C for PHP. It provides you a set of helpers to write views in an easy way. Volt is highly integrated with other components of Phalcon, just as you can use it as a stand-alone component in your applications.

Volt is inspired by [Jinja](#), originally created by [Armin Ronacher](#). Therefore many developers will be in familiar territory using the same syntax they have been using with similar template engines. Volt's syntax and features have been enhanced with more elements and of course with the performance that developers have been accustomed to while working with Phalcon.

```

show.volt
1  {# app/views/products/show.volt #}
2  {% extends "templates/products.volt" %}

3
4  {{ content() }}

5
6  {% block last_products %}

7
8  {% for product in products %}
9      * Name: {{ product.name|e }}
10     {% if product.status == "Active" %}
11         Price: {{ product.price + product.taxes/100 }}
12         {{ link_to('More', 'products/details/' ~ product.id) }}
13     {% else %}
14         {{ '(Inactive)' }}
15     {% endif %}
16 {% endfor %}

17
18 {% endblock %}

19
20 {% block footer %}
21 {{ partial('navbar/footer') }}
22 {% endblock %}

```

2.20.1 Introduction

Volt views are compiled to pure PHP code, so basically they save the effort of writing PHP code manually:

```

{# app/views/products/show.volt #-}

{% block last_products %}

{% for product in products %}
    * Name: {{ product.name|e }}
    {% if product.status == "Active" %}
        Price: {{ product.price + product.taxes/100 }}
    {% endif %}
{% endfor %}

{% endblock %}

```

2.20.2 Activating Volt

As other template engines, you may register Volt in the view component, using a new extension or reusing the standard .phml:

```

<?php

use Phalcon\Mvc\View;

//Registering Volt as template engine
$di->set('view', function() {

    $view = new View();

```

```

$view->setViewsDir('..../app/views/');
$view->registerEngines(array(
    '.volt' => 'Phalcon\Mvc\View\Engine\Volt'
));
return $view;
);

```

Use the standard ”.phtml” extension:

```

<?php

$view->registerEngines(array(
    '.phtml' => 'Phalcon\Mvc\View\Engine\Volt'
));

```

2.20.3 Basic Usage

A view consists of Volt code, PHP and HTML. A set of special delimiters is available to enter into Volt mode. { % ... % } is used to execute statements such as for-loops or assign values and { { ... } }, prints the result of an expression to the template.

Below is a minimal template that illustrates a few basics:

```

{# app/views/posts/show.phtml #-}
<!DOCTYPE html>
<html>
    <head>
        <title>{{ title }} - An example blog</title>
    </head>
    <body>

        {%
            if show_navigation %
                <ul id="navigation">
                    {%
                        for item in menu %
                            <li><a href="{{ item.href }}">{{ item.caption }}</a></li>
                        {%
                            endfor %
                        }
                    </ul>
            {%
                endif %
            }

            <h1>{{ post.title }}</h1>

            <div class="content">
                {{ post.content }}
            </div>

        </body>
    </html>

```

Using Phalcon\Mvc\View you can pass variables from the controller to the views. In the above example, three variables were passed to the view: title, menu and post:

```

<?php

use Phalcon\Mvc\Controller;

```

```
class PostsController extends Controller
{
    public function showAction()
    {
        $post = Post::findFirst();

        $this->view->title      = $post->title;
        $this->view->post         = $post;
        $this->view->menu         = Menu::find();
        $this->view->show_navigation = true;
    }
}
```

2.20.4 Variables

Object variables may have attributes which can be accessed using the syntax: foo.bar. If you are passing arrays, you have to use the square bracket syntax: foo['bar']

```
{{ post.title }} {{ post['title'] }}
```

2.20.5 Filters

Variables can be formatted or modified using filters. The pipe operator | is used to apply filters to variables:

```
{{ post.title|e }}
{{ post.content|striptags }}
{{ name|capitalize|trim }}
```

The following is the list of available built-in filters in Volt:

Filter	Description
e	Applies Phalcon\Escaper->escapeHtml to the value
escape	Applies Phalcon\Escaper->escapeHtml to the value
escape_css	Applies Phalcon\Escaper->escapeCss to the value
escape_js	Applies Phalcon\Escaper->escapeJs to the value
escape_attr	Applies Phalcon\Escaper->escapeHtmlAttr to the value
trim	Applies the <code>trim</code> PHP function to the value. Removing extra spaces
left_trim	Applies the <code>ltrim</code> PHP function to the value. Removing extra spaces
right_trim	Applies the <code>rtrim</code> PHP function to the value. Removing extra spaces
striptags	Applies the <code>striptags</code> PHP function to the value. Removing HTML tags
slashes	Applies the <code>slashes</code> PHP function to the value. Escaping values
stripslashes	Applies the <code>stripslashes</code> PHP function to the value. Removing escaped quotes
capitalize	Capitalizes a string by applying the <code>ucwords</code> PHP function to the value
lower	Change the case of a string to lowercase
upper	Change the case of a string to uppercase
length	Counts the string length or how many items are in an array or object
nl2br	Changes newlines \n by line breaks (). Uses the PHP function <code>nl2br</code>
sort	Sorts an array using the PHP function <code>asort</code>
keys	Returns the array keys using <code>array_keys</code>
join	Joins the array parts using a separator <code>join</code>
format	Formats a string using <code>sprintf</code> .
json_encode	Converts a value into its <code>JSON</code> representation
json_decode	Converts a value from its <code>JSON</code> representation to a PHP representation
abs	Applies the <code>abs</code> PHP function to a value.
url_encode	Applies the <code>urlencode</code> PHP function to the value
default	Sets a default value in case that the evaluated expression is empty (is not set or evaluates to a falsy value)
convert_encoding	Converts a string from one charset to another

Examples:

```

{# e or escape filter #}
{{ "<h1>Hello<h1>"|e }}
{{ "<h1>Hello<h1>"|escape }}

{# trim filter #}
{{ "    hello    "|trim }}

{# striptags filter #}
{{ "<h1>Hello<h1>"|striptags }}

{# slashes filter #}
{{ "'this is a string'"|slashes }}

{# stripslashes filter #}
{{ "\'this is a string\'"|stripslashes }}

{# capitalize filter #}
{{ "hello"|capitalize }}

{# lower filter #}
{{ "HELLO"|lower }}

{# upper filter #}
{{ "hello"|upper }} 
```

```

{# length filter #}
{{ "robots"|length }}
{{ [1, 2, 3]|length }}

{# nl2br filter #}
{{ "some\n\ttext"|nl2br }}

{# sort filter #}
{%- set sorted=[3, 1, 2]|sort %}

{# keys filter #}
{%- set keys=['first': 1, 'second': 2, 'third': 3]|keys %}

{# join filter #}
{%- "a".."z"|join(",") %}

{# format filter #}
{%- "My real name is %s"|format(name) %}

{# json_encode filter #}
{%- robots|json_encode %}

{# json_decode filter #}
{%- set decoded='{"one":1,"two":2,"three":3}'|json_decode %}

{# url_encode filter #}
{{ post.permanent_link|url_encode }}

{# convert_encoding filter #}
{{ "désolé"|convert_encoding('utf8', 'latin1') }}

```

2.20.6 Comments

Comments may also be added to a template using the {# ... #} delimiters. All text inside them is just ignored in the final output:

```

{# note: this is a comment
  %- set price = 100; %}
#}

```

2.20.7 List of Control Structures

Volt provides a set of basic but powerful control structures for use in templates:

For

Loop over each item in a sequence. The following example shows how to traverse a set of “robots” and print his/her name:

```

<h1>Robots</h1>
<ul>
  {%- for robot in robots %}
    <li>{{ robot.name|e }}</li>

```

```
{% endfor %}
</ul>
```

for-loops can also be nested:

```
<h1>Robots</h1>
{%
    for robot in robots %
        {%
            for part in robot.parts %
                Robot: {{ robot.name|e }} Part: {{ part.name|e }} <br/>
        %endfor %
    %endfor %
}
```

You can get the element “keys” as in the PHP counterpart using the following syntax:

```
{%
    set numbers = ['one': 1, 'two': 2, 'three': 3] %

    for name, value in numbers %
        Name: {{ name }} Value: {{ value }}
    %endfor %
}
```

An “if” evaluation can be optionally set:

```
{%
    set numbers = ['one': 1, 'two': 2, 'three': 3] %

    for value in numbers if value < 2 %
        Value: {{ value }}
    %endfor %

    for name, value in numbers if name != 'two' %
        Name: {{ name }} Value: {{ value }}
    %endfor %
}
```

If an ‘else’ is defined inside the ‘for’, it will be executed if the expression in the iterator result in zero iterations:

```
<h1>Robots</h1>
{%
    for robot in robots %
        Robot: {{ robot.name|e }} Part: {{ part.name|e }} <br/>
    %else %
        There are no robots to show
    %endfor %
}
```

Alternative syntax:

```
<h1>Robots</h1>
{%
    for robot in robots %
        Robot: {{ robot.name|e }} Part: {{ part.name|e }} <br/>
    %elsefor %
        There are no robots to show
    %endfor %
}
```

Loop Controls

The ‘break’ and ‘continue’ statements can be used to exit from a loop or force an iteration in the current block:

```
{# skip the even robots #
{%
    for index, robot in robots %
        {%
            if index is even %
                {%
                    continue %
                }
            {%
                endif %
            }
        }
    %endfor %
}
```

```

    ...
{%- endfor %}

{# exit the foreach on the first even robot #}
{%- for index, robot in robots %}
    {%- if index is even %}
        {%- break %}
    {%- endif %}
    ...
{%- endfor %}

```

If

As PHP, an “if” statement checks if an expression is evaluated as true or false:

```

<h1>Cyborg Robots</h1>
<ul>
{%- for robot in robots %}
    {%- if robot.type == "cyborg" %}
        <li>{{ robot.name|e }}</li>
    {%- endif %}
{%- endfor %}
</ul>

```

The else clause is also supported:

```

<h1>Robots</h1>
<ul>
{%- for robot in robots %}
    {%- if robot.type == "cyborg" %}
        <li>{{ robot.name|e }}</li>
    {%- else %}
        <li>{{ robot.name|e }} (not a cyborg)</li>
    {%- endif %}
{%- endfor %}
</ul>

```

The ‘elseif’ control flow structure can be used together with if to emulate a ‘switch’ block:

```

{%- if robot.type == "cyborg" %}
    Robot is a cyborg
{%- elseif robot.type == "virtual" %}
    Robot is virtual
{%- elseif robot.type == "mechanical" %}
    Robot is mechanical
{%- endif %}

```

Loop Context

A special variable is available inside ‘for’ loops providing you information about

Variable	Description
loop.index	The current iteration of the loop. (1 indexed)
loop.index0	The current iteration of the loop. (0 indexed)
loop.revindex	The number of iterations from the end of the loop (1 indexed)
loop.revindex0	The number of iterations from the end of the loop (0 indexed)
loop.first	True if in the first iteration.
loop.last	True if in the last iteration.
loop.length	The number of items to iterate

```
{% for robot in robots %}
  {% if loop.first %}
    <table>
      <tr>
        <th>#</th>
        <th>Id</th>
        <th>Name</th>
      </tr>
  {% endif %}
    <tr>
      <td>{{ loop.index }}</td>
      <td>{{ robot.id }}</td>
      <td>{{ robot.name }}</td>
    </tr>
  {% if loop.last %}
    </table>
  {% endif %}
{% endfor %}
```

2.20.8 Assignments

Variables may be changed in a template using the instruction “set”:

```
{% set fruits = ['Apple', 'Banana', 'Orange'] %}
{% set name = robot.name %}
```

Multiple assignments are allowed in the same instruction:

```
{% set fruits = ['Apple', 'Banana', 'Orange'], name = robot.name, active = true %}
```

Additionally, you can use compound assignment operators:

```
{% set price += 100.00 %}
{% set age *= 5 %}
```

The following operators are available:

Operator	Description
=	Standard Assignment
+=	Addition assignment
-=	Subtraction assignment
*=	Multiplication assignment
/=	Division assignment

2.20.9 Expressions

Volt provides a basic set of expression support, including literals and common operators.

A expression can be evaluated and printed using the ‘{{‘ and ‘}}’ delimiters:

```
{{ (1 + 1) * 2 }}
```

If an expression needs to be evaluated without be printed the ‘do’ statement can be used:

```
{% do (1 + 1) * 2 %}
```

Literals

The following literals are supported:

Filter	Description
“this is a string”	Text between double quotes or single quotes are handled as strings
100.25	Numbers with a decimal part are handled as doubles/floats
100	Numbers without a decimal part are handled as integers
false	Constant “false” is the boolean false value
true	Constant “true” is the boolean true value
null	Constant “null” is the Null value

Arrays

Whether you’re using PHP 5.3 or >= 5.4 you can create arrays by enclosing a list of values in square brackets:

```
"># Simple array #
{{ ['Apple', 'Banana', 'Orange'] }}

# Other simple array #
{{ ['Apple', 1, 2.5, false, null] }}

# Multi-Dimensional array #
{{ [[1, 2], [3, 4], [5, 6]] }}

# Hash-style array #
{{ ['first': 1, 'second': 4/2, 'third': '3'] }}
```

Curly braces also can be used to define arrays or hashes:

```
{% set myArray = ['Apple', 'Banana', 'Orange'] %}
{% set myHash = {'first': 1, 'second': 4/2, 'third': '3'} %}
```

Math

You may make calculations in templates using the following operators:

Operator	Description
+	Perform an adding operation. {{ 2 + 3 }} returns 5
-	Perform a subtraction operation {{ 2 - 3 }} returns -1
*	Perform a multiplication operation {{ 2 * 3 }} returns 6
/	Perform a division operation {{ 10 / 2 }} returns 5
%	Calculate the remainder of an integer division {{ 10 % 3 }} returns 1

Comparisons

The following comparison operators are available:

Operator	Description
<code>==</code>	Check whether both operands are equal
<code>!=</code>	Check whether both operands aren't equal
<code><></code>	Check whether both operands aren't equal
<code>></code>	Check whether left operand is greater than right operand
<code><</code>	Check whether left operand is less than right operand
<code><=</code>	Check whether left operand is less or equal than right operand
<code>>=</code>	Check whether left operand is greater or equal than right operand
<code>====</code>	Check whether both operands are identical
<code>!==</code>	Check whether both operands aren't identical

Logic

Logic operators are useful in the “if” expression evaluation to combine multiple tests:

Operator	Description
<code>or</code>	Return true if the left or right operand is evaluated as true
<code>and</code>	Return true if both left and right operands are evaluated as true
<code>not</code>	Negates an expression
<code>(expr)</code>	Parenthesis groups expressions

Other Operators

Additional operators seen the following operators are available:

Operator	Description
<code>~</code>	Concatenates both operands <code>\{\{ "hello" ~ "world" \}\}</code>
<code> </code>	Applies a filter in the right operand to the left <code>\{\{ "hello" uppercase \}\}</code>
<code>..</code>	Creates a range <code>\{\{ 'a'..'z' \}\} \{\{ 1..10 \}\}</code>
<code>is</code>	Same as <code>==</code> (equals), also performs tests
<code>in</code>	To check if an expression is contained into other expressions if “a” in “abc”
<code>is not</code>	Same as <code>!=</code> (not equals)
<code>'a' ? 'b' : 'c'</code>	Ternary operator. The same as the PHP ternary operator
<code>++</code>	Increments a value
<code>-</code>	Decrements a value

The following example shows how to use operators:

```
{% set robots = ['Voltron', 'Astro Boy', 'Terminator', 'C3PO'] %}

{% for index in 0..robots|length %}
    {% if robots[index] is defined %}
        {{ "Name: " ~ robots[index] }}
    {% endif %}
{% endfor %}
```

2.20.10 Tests

Tests can be used to test if a variable has a valid expected value. The operator “is” is used to perform the tests:

```
{% set robots = ['1': 'Voltron', '2': 'Astro Boy', '3': 'Terminator', '4': 'C3PO'] %}

{% for position, name in robots %}
    {% if position is odd %}
        {{ name }}
    {% endif %}
{% endfor %}
```

The following built-in tests are available in Volt:

Test	Description
defined	Checks if a variable is defined (isset)
empty	Checks if a variable is empty
even	Checks if a numeric value is even
odd	Checks if a numeric value is odd
numeric	Checks if value is numeric
scalar	Checks if value is scalar (not an array or object)
iterable	Checks if a value is iterable. Can be traversed by a “for” statement
divisibleby	Checks if a value is divisible by other value
sameas	Checks if a value is identical to other value
type	Checks if a value is of the specified type

More examples:

```
{% if robot is defined %}
    The robot variable is defined
{% endif %}

{% if robot is empty %}
    The robot is null or isn't defined
{% endif %}

{% for key, name in [1: 'Voltron', 2: 'Astroy Boy', 3: 'Bender'] %}
    {% if key is even %}
        {{ name }}
    {% endif %}
{% endfor %}

{% for key, name in [1: 'Voltron', 2: 'Astroy Boy', 3: 'Bender'] %}
    {% if key is odd %}
        {{ name }}
    {% endif %}
{% endfor %}

{% for key, name in [1: 'Voltron', 2: 'Astroy Boy', 'third': 'Bender'] %}
    {% if key is numeric %}
        {{ name }}
    {% endif %}
{% endfor %}

{% set robots = [1: 'Voltron', 2: 'Astroy Boy'] %}
{% if robots is iterable %}
    {% for robot in robots %}
        ...
    {% endfor %}
{% endif %}

{% set world = "hello" %}
```

```
{% if world is sameas("hello") %}
    {{ "it's hello" }}
{% endif %}

{% set external = false %}
{% if external is type('boolean') %}
    {{ "external is false or true" }}
{% endif %}
```

2.20.11 Macros

Macros can be used to reuse logic in a template, they act as PHP functions, can receive parameters and return values:

```
{%- macro related_bar(related_links) %}
<ul>
    {%- for rellink in related_links %}
        <li><a href="{{ url(link.url) }}" title="{{ link.title|striptags }}>{{ link.text }}</a>
    {%- endfor %}
</ul>
{%- endmacro %}

{# Print related links #}
{{ related_bar(links) }}

<div>This is the content</div>

{# Print related links again #}
{{ related_bar(links) }}
```

When calling macros, parameters can be passed by name:

```
{%- macro error_messages(message, field, type) %}
<div>
    <span class="error-type">{{ type }}</span>
    <span class="error-field">{{ field }}</span>
    <span class="error-message">{{ message }}</span>
</div>
{%- endmacro %}

{# Call the macro #}
{{ error_messages('type': 'Invalid', 'message': 'The name is invalid', 'field': 'name') }}
```

Macros can return values:

```
{%- macro my_input(name, class) %}
    {%- return text_field(name, 'class': class) %}
{%- endmacro %}

{# Call the macro #}
{{ '<p>' ~ my_input('name', 'input-text') ~ '</p>' }}
```

And receive optional parameters:

```
{%- macro my_input(name, class="input-text") %}
    {%- return text_field(name, 'class': class) %}
{%- endmacro %}

{# Call the macro #}
```

```
 {{ '<p>' ~ my_input('name') ~ '</p>' }}
 {{ '<p>' ~ my_input('name', 'input-text') ~ '</p>' }}
```

2.20.12 Using Tag Helpers

Volt is highly integrated with Phalcon\Tag, so it's easy to use the helpers provided by that component in a Volt template:

```
 {{ javascript_include("js/jquery.js") }}

 {{ form('products/save', 'method': 'post') }}

 <label for="name">Name</label>
 {{ text_field("name", "size": 32) }}

 <label for="type">Type</label>
 {{ select("type", productTypes, 'using': ['id', 'name']) }}

 {{ submit_button('Send') }}

 {{ end_form() }}
```

The following PHP is generated:

```
<?php echo Phalcon\Tag::javascriptInclude("js/jquery.js") ?>

<?php echo Phalcon\Tag::form(array('products/save', 'method' => 'post')) ; ?>

<label for="name">Name</label>
<?php echo Phalcon\Tag::textField(array('name', 'size' => 32)) ; ?>

<label for="type">Type</label>
<?php echo Phalcon\Tag::select(array('type', $productTypes, 'using' => array('id', 'name'))) ; ?>

<?php echo Phalcon\Tag::submitButton('Send') ; ?>

{{ end_form() }}
```

To call a Phalcon\Tag helper, you only need to call an uncamelized version of the method:

Method	Volt function
Phalcon\Tag::linkTo	link_to
Phalcon\Tag::textField	text_field
Phalcon\Tag::passwordField	password_field
Phalcon\Tag::hiddenField	hidden_field
Phalcon\Tag::fileField	file_field
Phalcon\Tag::checkField	check_field
Phalcon\Tag::radioField	radio_field
Phalcon\Tag::dateField	date_field
Phalcon\Tag::emailField	email_field
Phalcon\Tag::numberField	number_field
Phalcon\Tag::submitButton	submit_button
Phalcon\Tag::selectStatic	select_static
Phalcon\Tag::select	select
Phalcon\Tag::textArea	text_area
Phalcon\Tag::form	form
Phalcon\Tag::endForm	end_form
Phalcon\Tag::getTitle	get_title
Phalcon\Tag::stylesheetLink	stylesheet_link
Phalcon\Tag::javascriptInclude	javascript_include
Phalcon\Tag::image	image
Phalcon\Tag::friendlyTitle	friendly_title

2.20.13 Functions

The following built-in functions are available in Volt:

Name	Description
content	Includes the content produced in a previous rendering stage
get_content	Same as ‘content’
partial	Dynamically loads a partial view in the current template
super	Render the contents of the parent block
time	Calls the PHP function with the same name
date	Calls the PHP function with the same name
dump	Calls the PHP function ‘var_dump’
version	Returns the current version of the framework
constant	Reads a PHP constant
url	Generate a URL using the ‘url’ service

2.20.14 View Integration

Also, Volt is integrated with [Phalcon\Mvc\View](#), you can play with the view hierarchy and include partials as well:

```
{{ content() }}

<!-- Simple include of a partial -->
<div id="footer">{{ partial("partials/footer") }}</div>

<!-- Passing extra variables -->
<div id="footer">{{ partial("partials/footer", ['links': links]) }}</div>
```

A partial is included in runtime, Volt also provides “include”, this compiles the content of a view and returns its contents as part of the view which was included:

```
{# Simple include of a partial #}
<div id="footer">{<% include "partials/footer" %>}</div>

{# Passing extra variables #}
<div id="footer">{<% include "partials/footer" with ['links': links] %>}</div>
```

Include

‘include’ has a special behavior that will help us improve performance a bit when using Volt, if you specify the extension when including the file and it exists when the template is compiled, Volt can inline the contents of the template in the parent template where it’s included. Templates aren’t inlined if the ‘include’ have variables passed with ‘with’:

```
{# The contents of 'partials/footer.volt' is compiled and inlined #
<div id="footer">{<% include "partials/footer.volt" %>}</div>
```

2.20.15 Template Inheritance

With template inheritance you can create base templates that can be extended by others templates allowing to reuse code. A base template define *blocks* than can be overridden by a child template. Let’s pretend that we have the following base template:

```
{# templates/base.volt #
<!DOCTYPE html>
<html>
    <head>
        {<% block head %>
            <link rel="stylesheet" href="style.css" />
        {<% endblock %>
        <title>{<% block title %>} {<% endblock %>} - My Webpage</title>
    </head>
    <body>
        <div id="content">{<% block content %>} {<% endblock %>}</div>
        <div id="footer">
            {<% block footer %>&copy; Copyright 2015, All rights reserved.{<% endblock %>
        </div>
    </body>
</html>
```

From other template we could extend the base template replacing the blocks:

```
{<% extends "templates/base.volt" %>

{<% block title %>Index {<% endblock %>

{<% block head %><style type="text/css">.important { color: #336699; }</style> {<% endblock %>

{<% block content %>
    <h1>Index</h1>
    <p class="important">Welcome on my awesome homepage.</p>
{<% endblock %>
```

Not all blocks must be replaced at a child template, only those that are needed. The final output produced will be the following:

```
<!DOCTYPE html>
<html>
    <head>
        <style type="text/css">.important { color: #336699; }</style>
        <title>Index - My Webpage</title>
    </head>
    <body>
        <div id="content">
            <h1>Index</h1>
            <p class="important">Welcome on my awesome homepage.</p>
        </div>
        <div id="footer">
            &copy; Copyright 2015, All rights reserved.
        </div>
    </body>
</html>
```

Multiple Inheritance

Extended templates can extend other templates. The following example illustrates this:

```
{# main.volt #-}
<!DOCTYPE html>
<html>
    <head>
        <title>Title</title>
    </head>
    <body>
        {%- block content %}{% endblock %}
    </body>
</html>
```

Template “layout.volt” extends “main.volt”

```
{# layout.volt #-}
{%- extends "main.volt" %}

{%- block content %}

    <h1>Table of contents</h1>

{%- endblock %}
```

Finally a view that extends “layout.volt”:

```
{# index.volt #-}
{%- extends "layout.volt" %}

{%- block content %}

    {{ super() }}

    <ul>
        <li>Some option</li>
        <li>Some other option</li>
    </ul>

{%- endblock %}
```

Rendering “index.volt” produces:

```
<!DOCTYPE html>
<html>
  <head>
    <title>Title</title>
  </head>
  <body>

    <h1>Table of contents</h1>

    <ul>
      <li>Some option</li>
      <li>Some other option</li>
    </ul>

  </body>
</html>
```

Note the call to the function “super()”. With that function it’s possible to render the contents of the parent block.

As partials, the path set to “extends” is a relative path under the current views directory (i.e. app/views/).

By default, and for performance reasons, Volt only checks for changes in the children templates to know when to re-compile to plain PHP again, so it is recommended initialize Volt with the option ‘compileAlways’ => true. Thus, the templates are compiled always taking into account changes in the parent templates.

2.20.16 Autoescape mode

You can enable auto-escaping of all variables printed in a block using the autoescape mode:

```
Manually escaped: {{ robot.name|e }}

{%
  autoescape true %
}
Autoescaped: {{ robot.name }}
{%
  autoescape false %
}
No Autoescaped: {{ robot.name }}
{%
  endautoescape %
}
{%
  endautoescape %
}
```

2.20.17 Setting up the Volt Engine

Volt can be configured to alter its default behavior, the following example explain how to do that:

```
<?php

use Phalcon\Mvc\View;
use Phalcon\Mvc\View\Engine\Volt;

//Register Volt as a service
$di->set('voltService', function($view, $di) {

    $volt = new Volt($view, $di);

    $volt->setOptions(array(
        "compiledPath" => "../app/compiled-templates/",
    ));
});
```

```

        ".compiledExtension" => ".compiled"
    ));

    return $volt;
});

//Register Volt as template engine
$di->set('view', function() {

    $view = new View();

    $view->setViewsDir('../app/views/');

    $view->registerEngines(array(
        ".volt" => 'voltService'
    ));

    return $view;
});

```

If you do not want to reuse Volt as a service you can pass an anonymous function to register the engine instead of a service name:

```

<?php

use Phalcon\Mvc\View;
use Phalcon\Mvc\View\Engine\Volt;

//Register Volt as template engine with an anonymous function
$di->set('view', function() {

    $view = new View();

    $view->setViewsDir('../app/views/');

    $view->registerEngines(array(
        ".volt" => function($view, $di) {
            $volt = new Volt($view, $di);

            //set some options here

            return $volt;
        }
    ));

    return $view;
});

```

The following options are available in Volt:

The compilation path is generated according to the above options, if the developer wants total freedom defining the compilation path, an anonymous function can be used to generate it, this function receives the relative path to the template in the views directory. The following examples show how to change the compilation path dynamically:

```

<?php

// Just append the .php extension to the template path
// leaving the compiled templates in the same directory
$volt->setOptions(array(

```

```
'compiledPath' => function($templatePath) {
    return $templatePath . '.php';
}
));

// Recursively create the same structure in another directory
$volt->setOptions(array(
    'compiledPath' => function($templatePath) {
        $dirName = dirname($templatePath);
        if (!is_dir('cache/' . $dirName)) {
            mkdir('cache/' . $dirName);
        }
        return 'cache/' . $dirName . '/' . $templatePath . '.php';
}
));
)
```

2.20.18 Extending Volt

Unlike other template engines, Volt itself is not required to run the compiled templates. Once the templates are compiled there is no dependence on Volt. With performance independence in mind, Volt only acts as a compiler for PHP templates.

The Volt compiler allow you to extend it adding more functions, tests or filters to the existing ones.

Functions

Functions act as normal PHP functions, a valid string name is required as function name. Functions can be added using two strategies, returning a simple string or using an anonymous function. Always is required that the chosen strategy returns a valid PHP string expression:

```
<?php

use Phalcon\Mvc\View\Engine\Volt;

$volt = new Volt($view, $di);

$compiler = $volt->getCompiler();

// This binds the function name 'shuffle' in Volt to the PHP function 'str_shuffle'
$compiler->addFunction('shuffle', 'str_shuffle');
```

Register the function with an anonymous function. This case we use `$resolvedArgs` to pass the arguments exactly as were passed in the arguments:

```
<?php

$compiler->addFunction('widget', function($resolvedArgs, $exprArgs) {
    return 'MyLibrary\Widgets::get(' . $resolvedArgs . ')';
});
```

Treat the arguments independently and unresolved:

```
<?php

$compiler->addFunction('repeat', function($resolvedArgs, $exprArgs) use ($compiler) {
```

```
//Resolve the first argument
$firstArgument = $compiler->expression($exprArgs[0]['expr']);

//Checks if the second argument was passed
if (isset($exprArgs[1])) {
    $secondArgument = $compiler->expression($exprArgs[1]['expr']);
} else {
    //Use '10' as default
    $secondArgument = '10';
}

return 'str_repeat(' . $firstArgument . ', ' . $secondArgument . ')';
});
```

Generate the code based on some function availability:

```
<?php

$compiler->addFunction('contains_text', function($resolvedArgs, $exprArgs) {
    if (function_exists('mb_stripos')) {
        return 'mb_stripos(' . $resolvedArgs . ')';
    } else {
        return 'stripos(' . $resolvedArgs . ')';
    }
});
```

Built-in functions can be overridden adding a function with its name:

```
<?php

//Replace built-in function dump
$compiler->addFunction('dump', 'print_r');
```

Filters

A filter has the following form in a template: leftExpr|name(optional-args). Adding new filters is similar as seen with the functions:

```
<?php

//This creates a filter 'hash' that uses the PHP function 'md5'
$compiler->addFilter('hash', 'md5');
```

```
<?php

$compiler->addFilter('int', function($resolvedArgs, $exprArgs) {
    return 'intval(' . $resolvedArgs . ')';
});
```

Built-in filters can be overridden adding a function with its name:

```
<?php

//Replace built-in filter 'capitalize'
$compiler->addFilter('capitalize', 'lcfirst');
```

Extensions

With extensions the developer has more flexibility to extend the template engine, and override the compilation of a specific instruction, change the behavior of an expression or operator, add functions/filters, and more.

An extension is a class that implements the events triggered by Volt as a method of itself.

For example, the class below allows to use any PHP function in Volt:

```
<?php

class PhpFunctionExtension
{
    /**
     * This method is called on any attempt to compile a function call
     */
    public function compileFunction($name, $arguments)
    {
        if (function_exists($name)) {
            return $name . '(' . $arguments . ')';
        }
    }
}
```

The above class implements the method ‘compileFunction’ which is invoked before any attempt to compile a function call in any template. The purpose of the extension is to verify if a function to be compiled is a PHP function allowing to call it from the template. Events in extensions must return valid PHP code, this will be used as result of the compilation instead of the one generated by Volt. If an event doesn’t return a string the compilation is done using the default behavior provided by the engine.

The following compilation events are available to be implemented in extensions:

Event/Method	Description
compileFunction	Triggered before trying to compile any function call in a template
compileFilter	Triggered before trying to compile any filter call in a template
resolveExpression	Triggered before trying to compile any expression. This allows the developer to override operators
compileStatement	Triggered before trying to compile any expression. This allows the developer to override any statement

Volt extensions must be registered in the compiler making them available in compile time:

```
<?php

//Register the extension in the compiler
$compiler->addExtension(new PhpFunctionExtension());
```

2.20.19 Caching view fragments

With Volt it's easy cache view fragments. This caching improves performance preventing that the contents of a block from being executed by PHP each time the view is displayed:

```
{% cache "sidebar" %}
    <!-- generate this content is slow so we are going to cache it -->
{%- endcache %}
```

Setting a specific number of seconds:

```
{# cache the sidebar by 1 hour #}
{%
cache "sidebar" 3600 %}
<!-- generate this content is slow so we are going to cache it -->
{%
endcache %}
```

Any valid expression can be used as cache key:

```
{%
cache ("article-" ~ post.id) 3600 %}

<h1>{{ post.title }}</h1>

<p>{{ post.content }}</p>

{%
endcache %}
```

The caching is done by the `Phalcon\Cache` component via the view component. Learn more about how this integration works in the section “[Caching View Fragments](#)”.

2.20.20 Inject Services into a Template

If a service container (DI) is available for Volt, you can use the services by only accessing the name of the service in the template:

```
{# Inject the 'flash' service #}
<div id="messages">{{ flash.output() }}</div>

{# Inject the 'security' service #}
<input type="hidden" name="token" value="{{ security.getToken() }}">
```

2.20.21 Stand-alone component

Using Volt in a stand-alone mode can be demonstrated below:

```
<?php

use Phalcon\Mvc\View\Engine\Volt\Compiler as VoltCompiler;

//Create a compiler
$compiler = new VoltCompiler();

//Optionally add some options
$compiler->setOptions(array(
    //...
));

//Compile a template string returning PHP code
echo $compiler->compileString('{{ "hello" }}');

//Compile a template in a file specifying the destination file
$compiler->compileFile('layouts/main.volt', 'cache/layouts/main.volt.php');

//Compile a template in a file based on the options passed to the compiler
$compiler->compile('layouts/main.volt');

//Require the compiled templated (optional)
require $compiler->getCompiledTemplatePath();
```

2.20.22 External Resources

- A bundle for Sublime/Textmate is available [here](#)
- [Album-O-Rama](#) is a sample application using Volt as template engine, [[Github](#)]
- Our website is running using Volt as template engine, [[Github](#)]
- [Phosphorum](#), the Phalcon's forum, also uses Volt, [[Github](#)]
- [Vökuró](#), is another sample application that use Volt, [[Github](#)]

2.21 MVC Applications

All the hard work behind orchestrating the operation of MVC in Phalcon is normally done by [Phalcon\Mvc\Application](#). This component encapsulates all the complex operations required in the background, instantiating every component needed and integrating it with the project, to allow the MVC pattern to operate as desired.

2.21.1 Single or Multi Module Applications

With this component you can run various types of MVC structures:

Single Module

Single MVC applications consist of one module only. Namespaces can be used but are not necessary. An application like this would have the following file structure:

```
single/
  app/
    controllers/
    models/
    views/
  public/
    css/
    img/
    js/
```

If namespaces are not used, the following bootstrap file could be used to orchestrate the MVC flow:

```
<?php

use Phalcon\Loader;
use Phalcon\Mvc\View;
use Phalcon\Mvc\Application;
use Phalcon\DI\FactoryDefault;

$loader = new Loader();

$loader->registerDirs(
    array(
        '../apps/controllers/',
        '../apps/models/'
    )
)->register();
```

```

$di = new FactoryDefault();

// Registering the view component
$di->set('view', function() {
    $view = new View();
    $view->setViewsDir('../apps/views/');
    return $view;
});

try {
    $application = new Application($di);

    echo $application->handle()->getContent();
} catch (\Exception $e) {
    echo $e->getMessage();
}

```

If namespaces are used, the following bootstrap can be used:

```

<?php

use Phalcon\Loader;
use Phalcon\Mvc\View;
use Phalcon\Mvc\Dispatcher;
use Phalcon\Mvc\Application;
use Phalcon\DI\FactoryDefault;

$loader = new Loader();

// Use autoloading with namespaces prefixes
$loader->registerNamespaces(
    array(
        'Single\Controllers' => '../apps/controllers/',
        'Single\Models'       => '../apps/models/',
    )
)->register();

$di = new FactoryDefault();

// Register the dispatcher setting a Namespace for controllers
$di->set('dispatcher', function() {
    $dispatcher = new Dispatcher();
    $dispatcher->setDefaultNamespace('Single\Controllers');
    return $dispatcher;
});

// Registering the view component
$di->set('view', function() {
    $view = new View();
    $view->setViewsDir('../apps/views/');
    return $view;
});

try {
    $application = new Application($di);
}

```

```
echo $application->handle()->getContent();  
  
} catch(\Exception $e) {  
    echo $e->getMessage();  
}
```

Multi Module

A multi-module application uses the same document root for more than one module. In this case the following file structure can be used:

```
multiple/  
  apps/  
    frontend/  
      controllers/  
      models/  
      views/  
      Module.php  
    backend/  
      controllers/  
      models/  
      views/  
      Module.php  
  public/  
    css/  
    img/  
    js/
```

Each directory in apps/ have its own MVC structure. A Module.php is present to configure specific settings of each module like autoloaders or custom services:

```
<?php  
  
namespace Multiple\Backend;  
  
use Phalcon\Loader;  
use Phalcon\Mvc\View;  
use Phalcon\DiInterface;  
use Phalcon\Mvc\Dispatcher;  
use Phalcon\Mvc\ModuleDefinitionInterface;  
  
class Module implements ModuleDefinitionInterface  
{  
  
    /**  
     * Register a specific autoloader for the module  
     */  
    public function registerAutoloaders()  
    {  
  
        $loader = new Loader();  
  
        $loader->registerNamespaces(  
            array(  
                'Multiple\Backend\Controllers' => '../apps/backend/controllers/',  
                'Multiple\Backend\Models'      => '../apps/backend/models/',  
            )  
        );  
    }  
}
```

```

    );

    $loader->register();
}

/**
 * Register specific services for the module
 */
public function registerServices(DiInterface $di)
{
    // Registering a dispatcher
    $di->set('dispatcher', function() {
        $dispatcher = new Dispatcher();
        $dispatcher->setDefaultNamespace("Multiple\Backend\Controllers");
        return $dispatcher;
    });

    // Registering the view component
    $di->set('view', function() {
        $view = new View();
        $view->setViewsDir('../apps/backend/views/');
        return $view;
    });
}
}

```

A special bootstrap file is required to load the a multi-module MVC architecture:

```

<?php

use Phalcon\Mvc\Router;
use Phalcon\Mvc\Application;
use Phalcon\DI\FactoryDefault;

$di = new FactoryDefault();

// Specify routes for modules
$di->set('router', function () {

    $router = new Router();

    $router->setDefaultModule("frontend");

    $router->add("/login", array(
        'module'      => 'backend',
        'controller'  => 'login',
        'action'       => 'index',
    ));

    $router->add("/admin/products/:action", array(
        'module'      => 'backend',
        'controller'  => 'products',
        'action'       => 1,
    ));

    $router->add("/products/:action", array(
        'controller'  => 'products',
        'action'       => 1,
    ));
});

```

```
    return $router;
});

try {

    // Create an application
    $application = new Application($di);

    // Register the installed modules
    $application->registerModules(
        array(
            'frontend' => array(
                'className' => 'Multiple\Frontend\Module',
                'path'       => '../apps/frontend/Module.php',
            ),
            'backend'   => array(
                'className' => 'Multiple\Backend\Module',
                'path'       => '../apps/backend/Module.php',
            )
        )
    );

    // Handle the request
    echo $application->handle()->getContent();
}

} catch (\Exception $e) {
    echo $e->getMessage();
}
```

If you want to maintain the module configuration in the bootstrap file you can use an anonymous function to register the module:

```
<?php

use Phalcon\Mvc\View;

// Creating a view component
$view = new View();

// Set options to view component
//...

// Register the installed modules
$application->registerModules(
    array(
        'frontend' => function($di) use ($view) {
            $di->setShared('view', function() use ($view) {
                $view->setViewsDir('../apps/frontend/views/');
                return $view;
            });
        },
        'backend'   => function($di) use ($view) {
            $di->setShared('view', function() use ($view) {
                $view->setViewsDir('../apps/backend/views/');
                return $view;
            });
        }
    )
)
```

```
) ;
```

When `Phalcon\Mvc\Application` have modules registered, always is necessary that every matched route returns a valid module. Each registered module has an associated class offering functions to set the module itself up. Each module class definition must implement two methods: `registerAutoloaders()` and `registerServices()`, they will be called by `Phalcon\Mvc\Application` according to the module to be executed.

2.21.2 Understanding the default behavior

If you've been following the [tutorial](#) or have generated the code using [Phalcon Devtools](#), you may recognize the following bootstrap file:

```
<?php

use Phalcon\Mvc\Application;

try {

    // Register autoloaders
    //...

    // Register services
    //...

    // Handle the request
    $application = new Application($di);

    echo $application->handle()->getContent();

} catch (\Exception $e) {
    echo "Exception: ", $e->getMessage();
}
```

The core of all the work of the controller occurs when `handle()` is invoked:

```
<?php

echo $application->handle()->getContent();
```

2.21.3 Manual bootstrapping

If you do not wish to use `Phalcon\Mvc\Application`, the code above can be changed as follows:

```
<?php

// Get the 'router' service
$router = $di['router'];

$router->handle();

$view = $di['view'];

$dispatcher = $di['dispatcher'];

// Pass the processed router parameters to the dispatcher
$dispatcher->setControllerName($router->getControllerName());
```

```
$dispatcher->setActionName($router->getActionName());
$dispatcher->setParams($router->getParams());

// Start the view
$view->start();

// Dispatch the request
$dispatcher->dispatch();

// Render the related views
$view->render(
    $dispatcher->getControllerName(),
    $dispatcher->getActionName(),
    $dispatcher->getParams()
);

// Finish the view
$view->finish();

$response = $di['response'];

// Pass the output of the view to the response
$response->setContent($view->getContent());

// Send the response headers
$response->sendHeaders();

// Print the response
echo $response->getContent();
```

The following replacement of Phalcon\Mvc\Application lacks of a view component making it suitable for Rest APIs:

```
<?php

// Get the 'router' service
$router = $di['router'];

$router->handle();

$dispatcher = $di['dispatcher'];

// Pass the processed router parameters to the dispatcher
$dispatcher->setControllerName($router->getControllerName());
$dispatcher->setActionName($router->getActionName());
$dispatcher->setParams($router->getParams());

// Dispatch the request
$dispatcher->dispatch();

// Get the returned value by the latest executed action
$response = $dispatcher->getReturnedValue();

// Check if the action returned is a 'response' object
if ($response instanceof Phalcon\Http\ResponseInterface) {

    // Send the response
    $response->send();
}
```

Yet another alternative that catch exceptions produced in the dispatcher forwarding to other actions consequently:

```
<?php

// Get the 'router' service
$router = $di['router'];

$router->handle();

$dispatcher = $di['dispatcher'];

// Pass the processed router parameters to the dispatcher
$dispatcher->setControllerName($router->getControllerName());
$dispatcher->setActionName($router->getActionName());
$dispatcher->setParams($router->getParams());

try {
    // Dispatch the request
    $dispatcher->dispatch();
} catch (Exception $e) {
    // An exception has occurred, dispatch some controller/action aimed for that

    // Pass the processed router parameters to the dispatcher
    $dispatcher->setControllerName('errors');
    $dispatcher->setActionName('action503');

    // Dispatch the request
    $dispatcher->dispatch();
}

// Get the returned value by the latest executed action
$response = $dispatcher->getReturnedValue();

// Check if the action returned is a 'response' object
if ($response instanceof Phalcon\Http\ResponseInterface) {

    // Send the response
    $response->send();
}
```

Although the above implementations are a lot more verbose than the code needed while using [Phalcon\Mvc\Application](#), it offers an alternative in bootstrapping your application. Depending on your needs, you might want to have full control of what should be instantiated or not, or replace certain components with those of your own to extend the default functionality.

2.21.4 Application Events

[Phalcon\Mvc\Application](#) is able to send events to the [EventsManager](#) (if it is present). Events are triggered using the type “application”. The following events are supported:

Event Name	Triggered
boot	Executed when the application handles its first request
beforeStartModule	Before initialize a module, only when modules are registered
afterStartModule	After initialize a module, only when modules are registered
beforeHandleRequest	Before execute the dispatch loop
afterHandleRequest	After execute the dispatch loop

The following example demonstrates how to attach listeners to this component:

```
<?php

use Phalcon\Events\Manager as EventsManager;

$eventsManager = new EventsManager();

$application->setEventsManager($eventsManager);

$eventsManager->attach(
    "application",
    function($event, $application) {
        // ...
    }
);
```

2.21.5 External Resources

- MVC examples on Github

2.22 Routing

The router component allows defining routes that are mapped to controllers or handlers that should receive the request. A router simply parses a URI to determine this information. The router has two modes: MVC mode and match-only mode. The first mode is ideal for working with MVC applications.

2.22.1 Defining Routes

Phalcon\\Mvc\\Router provides advanced routing capabilities. In MVC mode, you can define routes and map them to controllers/actions that you require. A route is defined as follows:

```
<?php

use Phalcon\Mvc\Router;

// Create the router
$router = new Router();

//Define a route
$router->add(
    "/admin/users/my-profile",
    array(
        "controller" => "users",
        "action"      => "profile",
    )
);
```

```
//Another route
$router->add(
    "/admin/users/change-password",
    array(
        "controller" => "users",
        "action"      => "changePassword",
    )
);

$router->handle();
```

The method add() receives as first parameter a pattern and optionally a set of paths as second parameter. In this case, if the URI is exactly: /admin/users/my-profile, then the “users” controller with its action “profile” will be executed. Currently, the router does not execute the controller and action, it only collects this information to inform the correct component (ie. `Phalcon\Mvc\Dispatcher`) that this is controller/action it should to execute.

An application can have many paths, define routes one by one can be a cumbersome task. In these cases we can create more flexible routes:

```
<?php

use Phalcon\Mvc\Router;

// Create the router
$router = new Router();

//Define a route
$router->add(
    "/admin/:controller/:action/:params",
    array(
        "controller" => 1,
        "action"      => 2,
        "params"      => 3,
    )
);
```

In the example above, using wildcards we make a route valid for many URIs. For example, by accessing the following URL (/admin/users/a/delete/dave/301) then:

Controller	users
Action	delete
Parameter	dave
Parameter	301

The method add() receives a pattern that optionally could have predefined placeholders and regular expression modifiers. All the routing patterns must start with a slash character (/). The regular expression syntax used is the same as the [PCRE regular expressions](#). Note that, it is not necessary to add regular expression delimiters. All routes patterns are case-insensitive.

The second parameter defines how the matched parts should bind to the controller/action/parameters. Matching parts are placeholders or subpatterns delimited by parentheses (round brackets). In the example given above, the first subpattern matched (:controller) is the controller part of the route, the second the action and so on.

These placeholders help writing regular expressions that are more readable for developers and easier to understand. The following placeholders are supported:

Place-holder	Regular Expression	Usage
/:module	/([a-zA-Z0-9_-]+)	Matches a valid module name with alpha-numeric characters only
/:controller	/([a-zA-Z0-9_-]+)	Matches a valid controller name with alpha-numeric characters only
/:action	/([a-zA-Z0-9_-]+)	Matches a valid action name with alpha-numeric characters only
/:params	(/.*)*	Matches a list of optional words separated by slashes. Use only this placeholder at the end of a route
/:names-space	/([a-zA-Z0-9_-]+)	Matches a single level namespace name
/:int	/([0-9]+)	Matches an integer parameter

Controller names are camelized, this means that characters (-) and (_) are removed and the next character is uppercased. For instance, some_controller is converted to SomeController.

Since you can add many routes as you need using add(), the order in which routes are added indicate their relevance, latest routes added have more relevance than first added. Internally, all defined routes are traversed in reverse order until Phalcon\Mvc\Router finds the one that matches the given URI and processes it, while ignoring the rest.

Parameters with Names

The example below demonstrates how to define names to route parameters:

```
<?php

$router->add(
    "/news/([0-9]{4})/([0-9]{2})/([0-9]{2})/:params",
    array(
        "controller" => "posts",
        "action"      => "show",
        "year"        => 1, // ([0-9]{4})
        "month"       => 2, // ([0-9]{2})
        "day"         => 3, // ([0-9]{2})
        "params"      => 4, // :params
    )
);
```

In the above example, the route doesn't define a "controller" or "action" part. These parts are replaced with fixed values ("posts" and "show"). The user will not know the controller that is really dispatched by the request. Inside the controller, those named parameters can be accessed as follows:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function showAction()
    {
```

```
// Return "year" parameter
$year = $this->dispatcher->getParam("year");

// Return "month" parameter
$month = $this->dispatcher->getParam("month");

// Return "day" parameter
$day = $this->dispatcher->getParam("day");

}
```

Note that the values of the parameters are obtained from the dispatcher. This happens because it is the component that finally interacts with the drivers of your application. Moreover, there is also another way to create named parameters as part of the pattern:

```
<?php

$router->add(
    "/documentation/{chapter}/{name}.{type:[a-z]+}",
    array(
        "controller" => "documentation",
        "action"      => "show"
    )
);
```

You can access their values in the same way as before:

```
<?php

use Phalcon\Mvc\Controller;

class DocumentationController extends Controller
{

    public function showAction()
    {

        // Returns "name" parameter
        $name = $this->dispatcher->getParam("name");

        // Returns "type" parameter
        $type = $this->dispatcher->getParam("type");
    }
}
```

Short Syntax

If you don't like using an array to define the route paths, an alternative syntax is also available. The following examples produce the same result:

```
<?php

// Short form
```

```
$router->add("/posts/{year:[0-9]+}/{title:[a-z\-\-]+}", "Posts::show");

// Array form
$router->add(
    "/posts/([0-9]+)/([a-z\-\-]+)",
    array(
        "controller" => "posts",
        "action"      => "show",
        "year"        => 1,
        "title"       => 2,
    )
);
```

Mixing Array and Short Syntax

Array and short syntax can be mixed to define a route, in this case note that named parameters automatically are added to the route paths according to the position on which they were defined:

```
<?php

//First position must be skipped because it is used for
//the named parameter 'country'
$router->add('/news/{country:[a-z]{2}}/([a-z+])/([a-z\-\-])',
    array(
        'section' => 2, //Positions start with 2
        'article'  => 3
    )
);
```

Routing to Modules

You can define routes whose paths include modules. This is specially suitable to multi-module applications. It's possible define a default route that includes a module wildcard:

```
<?php

use Phalcon\Mvc\Router;

$router = new Router(false);

$router->add('/:module/:controller/:action/:params', array(
    'module'     => 1,
    'controller' => 2,
    'action'      => 3,
    'params'     => 4
));
```

In this case, the route always must have the module name as part of the URL. For example, the following URL: /admin/users/edit/sonny, will be processed as:

Module	admin
Controller	users
Action	edit
Parameter	sonny

Or you can bind specific routes to specific modules:

```
<?php

$router->add("/login", array(
    'module'      => 'backend',
    'controller'  => 'login',
    'action'       => 'index',
));

$router->add("/products/:action", array(
    'module'      => 'frontend',
    'controller'  => 'products',
    'action'       => 1,
));
)
```

Or bind them to specific namespaces:

```
<?php

$router->add("/:namespace/login", array(
    'namespace'   => 1,
    'controller'  => 'login',
    'action'       => 'index'
));
)
```

Namespaces/class names must be passed separated:

```
<?php

$router->add("/login", array(
    'namespace'   => 'Backend\Controllers',
    'controller'  => 'login',
    'action'       => 'index'
));
)
```

HTTP Method Restrictions

When you add a route using simply add(), the route will be enabled for any HTTP method. Sometimes we can restrict a route to a specific method, this is especially useful when creating RESTful applications:

```
<?php

// This route only will be matched if the HTTP method is GET
$router->addGet("/products/edit/{id}", "Products::edit");

// This route only will be matched if the HTTP method is POST
$router->addPost("/products/save", "Products::save");

// This route will be matched if the HTTP method is POST or PUT
$router->add("/products/update")->via(array("POST", "PUT"));
)
```

Using conversions

Conversions allow to freely transform the route's parameters before passing them to the dispatcher, the following examples show how to use them:

```
<?php

//The action name allows dashes, an action can be: /products/new-ipod-nano-4-generation
$router
    ->add('/products/{slug:[a-z\-]+}', array(
        'controller' => 'products',
        'action'      => 'show'
    ))
    ->convert('slug', function($slug) {
        //Transform the slug removing the dashes
        return str_replace('-', '', $slug);
    });
});
```

Groups of Routes

If a set of routes have common paths they can be grouped to easily maintain them:

```
<?php

use Phalcon\Mvc\Router;
use Phalcon\Mvc\Router\Group as RouterGroup;

$router = new Router();

//Create a group with a common module and controller
$blog = new RouterGroup(array(
    'module'      => 'blog',
    'controller'  => 'index'
));

//All the routes start with /blog
$blog->setPrefix('/blog');

//Add a route to the group
$blog->add('/save', array(
    'action' => 'save'
));

//Add another route to the group
$blog->add('/edit/{id}', array(
    'action' => 'edit'
));

//This route maps to a controller different than the default
$blog->add('/blog', array(
    'controller' => 'blog',
    'action'      => 'index'
));

//Add the group to the router
$router->mount($blog);
```

You can move groups of routes to separate files in order to improve the organization and code reusing in the application:

```
<?php

use Phalcon\Mvc\Router\Group as RouterGroup;
```

```

class BlogRoutes extends RouterGroup
{
    public function initialize()
    {
        //Default paths
        $this->setPaths(array(
            'module' => 'blog',
            'namespace' => 'Blog\Controllers'
        ));

        //All the routes start with /blog
        $this->setPrefix('/blog');

        //Add a route to the group
        $this->add('/save', array(
            'action' => 'save'
        ));

        //Add another route to the group
        $this->add('/edit/{id}', array(
            'action' => 'edit'
        ));

        //This route maps to a controller different than the default
        $this->add('/blog', array(
            'controller' => 'blog',
            'action' => 'index'
        ));
    }
}

```

Then mount the group in the router:

```

<?php

//Add the group to the router
$router->mount(new BlogRoutes());

```

2.22.2 Matching Routes

A valid URI must be passed to Router in order to let it checks the route that matches that given URI. By default, the routing URI is taken from the `$_GET['_url']` variable that is created by the rewrite engine module. A couple of rewrite rules that work very well with Phalcon are:

```

RewriteEngine On
RewriteCond %{REQUEST_FILENAME} !-d
RewriteCond %{REQUEST_FILENAME} !-f
RewriteRule ^(.*)$ index.php?_url=/\$1 [QSA,L]

```

The following example shows how to use this component in stand-alone mode:

```

<?php

use Phalcon\Mvc\Router;

// Creating a router

```

```
$router = new Router();

// Define routes here if any
// ...

// Taking URI from $_GET["_url"]
$router->handle();

// or Setting the URI value directly
$router->handle("/employees/edit/17");

// Getting the processed controller
echo $router->getControllerName();

// Getting the processed action
echo $router->getActionName();

//Get the matched route
$route = $router->getMatchedRoute();
```

2.22.3 Naming Routes

Each route that is added to the router is stored internally as an object `Phalcon\Mvc\Router\Route`. That class encapsulates all the details of each route. For instance, we can give a name to a path to identify it uniquely in our application. This is especially useful if you want to create URLs from it.

```
<?php

$route = $router->add("/posts/{year}/{title}", "Posts::show");

$route->setName("show-posts");

//or just

$route->add("/posts/{year}/{title}", "Posts::show")->setName("show-posts");
```

Then, using for example the component `Phalcon\Mvc\Url` we can build routes from its name:

```
<?php

// returns /posts/2012/phalcon-1-0-released
echo $url->get(array(
    "for"    => "show-posts",
    "year"   => "2012",
    "title"  => "phalcon-1-0-released"
));
```

2.22.4 Usage Examples

The following are examples of custom routes:

```
<?php

// matches "/system/admin/a/edit/7001"
$router->add(
    "/system/:controller/a/:action/:params",
```

```

array(
    "controller" => 1,
    "action"      => 2,
    "params"      => 3
)
);

// matches "/es/news"
$router->add(
    "/{[a-z]{2}}/:controller",
    array(
        "controller" => 2,
        "action"      => "index",
        "language"   => 1
    )
);

// matches "/es/news"
$router->add(
    "/{language:[a-z]{2}}/:controller",
    array(
        "controller" => 2,
        "action"      => "index"
    )
);

// matches "/admin/posts/edit/100"
$router->add(
    "/admin/:controller/:action/:int",
    array(
        "controller" => 1,
        "action"      => 2,
        "id"         => 3
    )
);

// matches "/posts/2010/02/some-cool-content"
$router->add(
    "/posts/({0-9}{4})/({0-9}{2})/([a-z\-\-]+)",
    array(
        "controller" => "posts",
        "action"      => "show",
        "year"        => 1,
        "month"       => 2,
        "title"       => 4
    )
);

// matches "/manual/en/translate.adapter.html"
$router->add(
    "/manual/({[a-z]{2}})/({a-z\.\-}+)\.html",
    array(
        "controller" => "manual",
        "action"      => "show",
        "language"   => 1,
        "file"        => 2
    )
);

```

```
// matches /feed/fr/le-robots-hot-news.atom
$router->add(
    "/feed/{lang:[a-z]+}/{blog:[a-z\-\-]+}\.{type:[a-z\-\-]+}",
    "Feed::get"
);

// matches /api/v1/users/peter.json
$router->add('/api/(v1|v2)/{method:[a-z]+}/{param:[a-z]+}\.(json|xml)',
    array(
        'controller' => 'api',
        'version'     => 1,
        'format'      => 4
    )
);
```

Beware of characters allowed in regular expression for controllers and namespaces. As these become class names and in turn they're passed through the file system could be used by attackers to read unauthorized files. A safe regular expression is: `/([a-zA-Z0-9_-]+)`

2.22.5 Default Behavior

Phalcon\\Mvc\\Router has a default behavior providing a very simple routing that always expects a URI that matches the following pattern: `/:controller/:action/:params`

For example, for a URL like this `http://phalconphp.com/documentation/show/about.html`, this router will translate it as follows:

Controller	documentation
Action	show
Parameter	about.html

If you don't want use this routes as default in your application, you must create the router passing false as parameter:

```
<?php

use Phalcon\Mvc\Router;

// Create the router without default routes
$router = new Router(false);
```

2.22.6 Setting the default route

When your application is accessed without any route, the `'/'` route is used to determine what paths must be used to show the initial page in your website/application:

```
<?php

$router->add("/", array(
    'controller' => 'index',
    'action'      => 'index'
));
```

2.22.7 Not Found Paths

If none of the routes specified in the router are matched, you can define a group of paths to be used in this scenario:

```
<?php

//Set 404 paths
$router->notFound(array(
    "controller" => "index",
    "action"      => "route404"
)) ;
```

2.22.8 Setting default paths

It's possible to define default values for common paths like module, controller or action. When a route is missing any of those paths they can be automatically filled by the router:

```
<?php

//Setting a specific default
$router->setDefaultModule('backend');
$router->setDefaultNamespace('Backend\Controllers');
$router->setDefaultController('index');
$router->setDefaultAction('index');

//Using an array
$router->setDefaults(array(
    'controller' => 'index',
    'action'      => 'index'
));
```

2.22.9 Dealing with extra/trailing slashes

Sometimes a route could be accessed with extra/trailing slashes and the end of the route, those extra slashes would lead to produce a not-found status in the dispatcher. You can set up the router to automatically remove the slashes from the end of handled route:

```
<?php

use Phalcon\Mvc\Router;

$router = new Router();

//Remove trailing slashes automatically
$router->removeExtraSlashes(true);
```

Or, you can modify specific routes to optionally accept trailing slashes:

```
<?php

$router->add(
    '/{language:[a-z]{2}}/:controller[/{0,1}]',
    array(
        'controller' => 2,
        'action'      => 'index'
    )
);
```

2.22.10 Match Callbacks

Sometimes, routes must be matched if they meet specific conditions, you can add arbitrary conditions to routes using the ‘beforeMatch’ callback, if this function return false, the route will be treated as non-matched:

```
<?php

$router->add('/login', array(
    'module'      => 'admin',
    'controller'  => 'session'
))->beforeMatch(function($uri, $route) {
    //Check if the request was made with Ajax
    if ($_SERVER['HTTP_X_REQUESTED_WITH'] == 'xmlhttprequest') {
        return false;
    }
    return true;
});
```

You can re-use these extra conditions in classes:

```
<?php

class AjaxFilter
{
    public function check()
    {
        return $_SERVER['HTTP_X_REQUESTED_WITH'] == 'xmlhttprequest';
    }
}
```

And use this class instead of the anonymous function:

```
<?php

$router->add('/get/info/{id}', array(
    'controller' => 'products',
    'action'      => 'info'
))->beforeMatch(array(new AjaxFilter(), 'check'));
```

2.22.11 Hostname Constraints

The router allow to set hostname constraints, this means that specific routes or a group of routes can be restricted to only match if the route also meets the hostname constraint:

```
<?php

$router->add('/login', array(
    'module'      => 'admin',
    'controller'  => 'session',
    'action'      => 'login'
))->setHostName('admin.company.com');
```

Hostname can also be regular expressions:

```
<?php

$router->add('/login', array(
    'module'      => 'admin',
```

```
'controller' => 'session',
'action'      => 'login'
))->setHostName('([a-z+]).company.com');
```

In groups of routes you can set up a hostname constraint that apply for every route in the group:

```
<?php

use Phalcon\Mvc\Router\Group as RouterGroup;

//Create a group with a common module and controller
$blog = new RouterGroup(array(
    'module'      => 'blog',
    'controller'  => 'posts'
));

//Hostname restriction
$blog->setHostName('blog.mycompany.com');

//All the routes start with /blog
$blog->setPrefix('/blog');

//Default route
$blog->add('/', array(
    'action'  => 'index'
));

//Add a route to the group
$blog->add('/save', array(
    'action'  => 'save'
));

//Add another route to the group
$blog->add('/edit/{id}', array(
    'action'  => 'edit'
));

//Add the group to the router
$router->mount($blog);
```

2.22.12 URI Sources

By default the URI information is obtained from the `$_GET['_url']` variable, this is passed by the Rewrite-Engine to Phalcon, you can also use `$_SERVER['REQUEST_URI']` if required:

```
<?php

use Phalcon\Mvc\Router;

...

$router->setUriSource(Router::URI_SOURCE_GET_URL); // use $_GET['_url'] (default)
$router->setUriSource(Router::URI_SOURCE_SERVER_REQUEST_URI); // use $_SERVER['REQUEST_URI'] (default)
```

Or you can manually pass a URI to the ‘handle’ method:

```
<?php  
  
$router->handle('/some/route/to/handle');
```

2.22.13 Testing your routes

Since this component has no dependencies, you can create a file as shown below to test your routes:

```
<?php  
  
use Phalcon\Mvc\Router;  
  
//These routes simulate real URIs  
$testRoutes = array(  
    '/',  
    '/index',  
    '/index/index',  
    '/index/test',  
    '/products',  
    '/products/index/',  
    '/products/show/101',  
);  
  
$router = new Router();  
  
//Add here your custom routes  
//...  
  
//Testing each route  
foreach ($testRoutes as $testRoute) {  
  
    //Handle the route  
    $router->handle($testRoute);  
  
    echo 'Testing ', $testRoute, '<br>';  
  
    //Check if some route was matched  
    if ($router->wasMatched()) {  
        echo 'Controller: ', $router->getControllerName(), '<br>';  
        echo 'Action: ', $router->getActionName(), '<br>';  
    } else {  
        echo 'The route wasn\'t matched by any route<br>';  
    }  
    echo '<br>';  
}
```

2.22.14 Annotations Router

This component provides a variant that's integrated with the [annotations](#) service. Using this strategy you can write the routes directly in the controllers instead of adding them in the service registration:

```
<?php  
  
use Phalcon\Mvc\Router\Annotations as RouterAnnotations;
```

```
$di['router'] = function() {
    //Use the annotations router
    $router = new RouterAnnotations(false);

    //Read the annotations from ProductsController if the uri starts with /api/products
    $router->addResource('Products', '/api/products');

    return $router;
};
```

The annotations can be defined in the following way:

```
<?php

/**
 * @RoutePrefix("/api/products")
 */
class ProductsController
{

    /**
     * @Get("/")
     */
    public function indexAction()
    {

    }

    /**
     * @Get("/edit/{id:[0-9]+}", name="edit-robot")
     */
    public function editAction($id)
    {

    }

    /**
     * @Route("/save", methods={"POST", "PUT"}, name="save-robot")
     */
    public function saveAction()
    {

    }

    /**
     * @Route("/delete/{id:[0-9]+}", methods="DELETE",
     *        conversors={id="MyConversors::checkId"})
     */
    public function deleteAction($id)
    {

    }

    public function infoAction($id)
    {

    }
}
```

```
}
```

Only methods marked with valid annotations are used as routes. List of annotations supported:

Name	Description	Usage
RoutePrefix	A prefix to be prepended to each route uri. This annotation must be placed at the class' docblock	@RoutePrefix("/api/products")
Route	This annotation marks a method as a route. This annotation must be placed in a method docblock	@Route("/api/products/show")
Get	This annotation marks a method as a route restricting the HTTP method to GET	@Get("/api/products/search")
Post	This annotation marks a method as a route restricting the HTTP method to POST	@Post("/api/products/save")
Put	This annotation marks a method as a route restricting the HTTP method to PUT	@Put("/api/products/save")
Delete	This annotation marks a method as a route restricting the HTTP method to DELETE	@Delete("/api/products/delete/{id}")
Options	This annotation marks a method as a route restricting the HTTP method to OPTIONS	@Option("/api/products/info")

For annotations that add routes, the following parameters are supported:

Name	Description	Usage
methods	Define one or more HTTP method that route must meet with	@Route("/api/products", methods={"GET", "POST"})
name	Define a name for the route	@Route("/api/products", name="get-products")
paths	An array of paths like the one passed to Phalcon\Mvc\Router::add	@Route("/posts/{id}/{slug}", paths={module="backend"})
convertors	A hash of converters to be applied to the parameters	@Route("/posts/{id}/{slug}", convertors={id="MyConverter::getId"})

If routes map to controllers in modules is better use the addModuleResource method:

```
<?php

use Phalcon\Mvc\Router\Annotations as RouterAnnotations;

$di['router'] = function() {

    //Use the annotations router
    $router = new RouterAnnotations(false);

    //Read the annotations from Backend\Controllers\ProductsController if the uri starts with /api/
    $router->addModuleResource('backend', 'Products', '/api/products');

    return $router;
};
```

2.22.15 Registering Router instance

You can register router during service registration with Phalcon dependency injector to make it available inside controller.

You need to add code below in your bootstrap file (for example index.php or app/config/services.php if you use Phalcon Developer Tools)

```
<?php

/**
 * add routing capabilities
*/
$di->set('router', function() {
    require __DIR__.'/../app/config/routes.php';
    return $router;
});
```

You need to create app/config/routes.php and add router initialization code, for example:

```
<?php

use Phalcon\Mvc\Router;

$router = new Router();

$router->add("/login", array(
    'controller' => 'login',
    'action'      => 'index',
));

$router->add("/products/:action", array(
    'controller' => 'products',
    'action'      => 1,
));

return $router;
```

2.22.16 Implementing your own Router

The `Phalcon\Mvc\RouterInterface` interface must be implemented to create your own router replacing the one provided by Phalcon.

2.23 Dispatching Controllers

`Phalcon\Mvc\Dispatcher` is the component responsible for instantiating controllers and executing the required actions on them in an MVC application. Understanding its operation and capabilities helps us get more out of the services provided by the framework.

2.23.1 The Dispatch Loop

This is an important process that has much to do with the MVC flow itself, especially with the controller part. The work occurs within the controller dispatcher. The controller files are read, loaded, and instantiated. Then the required actions are executed. If an action forwards the flow to another controller/action, the controller dispatcher starts again. To better illustrate this, the following example shows approximately the process performed within `Phalcon\Mvc\Dispatcher`:

```
<?php

//Dispatch loop
while (! $finished) {
```

```

$finished = true;

$controllerClass = $controllerName . "Controller";

//Instantiating the controller class via autoloaders
$controller = new $controllerClass();

// Execute the action
call_user_func_array(array($controller, $actionName . "Action"), $params);

// '$finished' should be reloaded to check if the flow
// was forwarded to another controller
$finished = true;
}

```

The code above lacks validations, filters and additional checks, but it demonstrates the normal flow of operation in the dispatcher.

Dispatch Loop Events

`Phalcon\Mvc\Dispatcher` is able to send events to an `EventsManager` if it is present. Events are triggered using the type “dispatch”. Some events when returning boolean false could stop the active operation. The following events are supported:

Event Name	Triggered	Can stop operation?	Triggered on
before-DispatchLoop	Triggered before entering in the dispatch loop. At this point the dispatcher don't know if the controller or the actions to be executed exist. The Dispatcher only knows the information passed by the Router.	Yes	Listeners
before-Dispatch	Triggered after entering in the dispatch loop. At this point the dispatcher don't know if the controller or the actions to be executed exist. The Dispatcher only knows the information passed by the Router.	Yes	Listeners
beforeExecuteRoute	Triggered before executing the controller/action method. At this point the dispatcher has been initialized the controller and know if the action exist.	Yes	Listeners/Controllers
initialize	Allow to globally initialize the controller in the request	No	Controllers
afterExecuteRoute	Triggered after executing the controller/action method. As operation cannot be stopped, only use this event to make clean up after execute the action	No	Listeners/Controllers
beforeNotFoundAction	Triggered when the action was not found in the controller	Yes	Listeners
beforeException	Triggered before the dispatcher throws any exception	Yes	Listeners
afterDispatch	Triggered after executing the controller/action method. As operation cannot be stopped, only use this event to make clean up after execute the action	Yes	Listeners
afterDispatchLoop	Triggered after exiting the dispatch loop	No	Listeners

The [INVO](#) tutorial shows how to take advantage of dispatching events implementing a security filter with [Acl](#)

The following example demonstrates how to attach listeners to this component:

```
<?php

use Phalcon\Mvc\Dispatcher as MvcDispatcher;
use Phalcon\Events\Manager as EventsManager;

$di->set('dispatcher', function() {

    //Create an event manager
    $eventsManager = new EventsManager();

    //Attach a listener for type "dispatch"
    $eventsManager->attach("dispatch", function($event, $dispatcher) {
        //...
    });

    $dispatcher = new MvcDispatcher();

    //Bind the eventsManager to the view component
    $dispatcher->setEventsManager($eventsManager);

    return $dispatcher;
}, true);
```

An instantiated controller automatically acts as a listener for dispatch events, so you can implement methods as callbacks:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function beforeExecuteRoute($dispatcher)
    {
        // Executed before every found action
    }

    public function afterExecuteRoute($dispatcher)
    {
        // Executed after every found action
    }
}
```

2.23.2 Forwarding to other actions

The dispatch loop allows us to forward the execution flow to another controller/action. This is very useful to check if the user can access to certain options, redirect users to other screens or simply reuse code.

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{
```

```
public function indexAction()
{
}

public function saveAction($year, $postTitle)
{
    // .. store some product and forward the user

    // Forward flow to the index action
    $this->dispatcher->forward(array(
        "controller" => "post",
        "action" => "index"
    ));
}
}
```

Keep in mind that making a “forward” is not the same as making an HTTP redirect. Although they apparently got the same result. The “forward” doesn’t reload the current page, all the redirection occurs in a single request, while the HTTP redirect needs two requests to complete the process.

More forwarding examples:

```
<?php

// Forward flow to another action in the current controller
$this->dispatcher->forward(array(
    "action" => "search"
));

// Forward flow to another action in the current controller
// passing parameters
$this->dispatcher->forward(array(
    "action" => "search",
    "params" => array(1, 2, 3)
));
```

A forward action accepts the following parameters:

Parameter	Triggered
controller	A valid controller name to forward to.
action	A valid action name to forward to.
params	An array of parameters for the action
namespace	A valid namespace name where the controller is part of

2.23.3 Preparing Parameters

Thanks to the hooks points provided by `Phalcon\Mvc\Dispatcher` you can easily adapt your application to any URL schema:

For example, you want your URLs look like: `http://example.com/controller/key1/value1/key2/value`

Parameters by default are passed as they come in the URL to actions, you can transform them to the desired schema:

```
<?php

use Phalcon\Dispatcher;
```

```

use Phalcon\Mvc\Dispatcher as MvcDispatcher;
use Phalcon\Events\Manager as EventsManager;

$di->set('dispatcher', function() {

    //Create an EventsManager
    $eventsManager = new EventsManager();

    //Attach a listener
    $eventsManager->attach("dispatch:beforeDispatchLoop", function($event, $dispatcher) {

        $keyParams = array();
        $params    = $dispatcher->getParams();

        //Use odd parameters as keys and even as values
        foreach ($params as $number => $value) {
            if ($number & 1) {
                $keyParams[$params[$number - 1]] = $value;
            }
        }

        //Override parameters
        $dispatcher->setParams($keyParams);
    });

    $dispatcher = new MvcDispatcher();
    $dispatcher->setEventsManager($eventsManager);

    return $dispatcher;
});

```

If the desired schema is: <http://example.com/controller/key1:value1/key2:value>, the following code is required:

```

<?php

use Phalcon\Dispatcher;
use Phalcon\Mvc\Dispatcher as MvcDispatcher;
use Phalcon\Events\Manager as EventsManager;

$di->set('dispatcher', function() {

    //Create an EventsManager
    $eventsManager = new EventsManager();

    //Attach a listener
    $eventsManager->attach("dispatch:beforeDispatchLoop", function($event, $dispatcher) {

        $keyParams = array();
        $params    = $dispatcher->getParams();

        //Explode each parameter as key,value pairs
        foreach ($params as $number => $value) {
            $parts          = explode(':', $value);
            $keyParams[$parts[0]] = $parts[1];
        }

        //Override parameters
        $dispatcher->setParams($keyParams);
    });

});

```

```
$dispatcher = new MvcDispatcher();
$dispatcher->setEventsManager($eventsManager);

return $dispatcher;
});
```

2.23.4 Getting Parameters

When a route provides named parameters you can receive them in a controller, a view or any other component that extends Phalcon\DI\Injectable.

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function saveAction()
    {

        // Get the post's title passed in the URL as parameter
        // or prepared in an event
        $title = $this->dispatcher->getParam("title");

        // Get the post's year passed in the URL as parameter
        // or prepared in an event also filtering it
        $year = $this->dispatcher->getParam("year", "int");

        // ...
    }
}
```

2.23.5 Preparing actions

You can also define an arbitrary schema for actions before be dispatched.

Camelize action names

If the original URL is: <http://example.com/admin/products/show-latest-products>, and for example you want to camelize ‘show-latest-products’ to ‘ShowLatestProducts’, the following code is required:

```
<?php

use Phalcon\Text;
use Phalcon\Mvc\Dispatcher as MvcDispatcher;
use Phalcon\Events\Manager as EventsManager;

$di->set('dispatcher', function() {
```

```

//Create an EventsManager
$eventsManager = new EventsManager();

//Camelize actions
$eventsManager->attach("dispatch:beforeDispatchLoop", function($event, $dispatcher) {
    $dispatcher->setActionName(Text::camelize($dispatcher->getActionName()));
});

$dispatcher = new MvcDispatcher();
$dispatcher->setEventsManager($eventsManager);

return $dispatcher;
});
}

```

Remove legacy extensions

If the original URL always contains a ‘.php’ extension:

<http://example.com/admin/products/show-latest-products.php> <http://example.com/admin/products/index.php>

You can remove it before dispatch the controller/action combination:

```

<?php

use Phalcon\Mvc\Dispatcher as MvcDispatcher;
use Phalcon\Events\Manager as EventsManager;

$di->set('dispatcher', function() {

    //Create an EventsManager
    $eventsManager = new EventsManager();

    //Remove extension before dispatch
    $eventsManager->attach("dispatch:beforeDispatchLoop", function($event, $dispatcher) {

        //Remove extension
        $action = preg_replace('/\.\php$/i', '', $dispatcher->getActionName());

        //Override action
        $dispatcher->setActionName($action);
    });

    $dispatcher = new MvcDispatcher();
    $dispatcher->setEventsManager($eventsManager);

    return $dispatcher;
});
}

```

Inject model instances

In this example, the developer wants to inspect the parameters that an action will receive in order to dynamically inject model instances.

The controller looks like:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{
    /**
     * Shows posts
     *
     * @param \Posts $post
     */
    public function showAction(Posts $post)
    {
        $this->view->post = $post;
    }
}
```

Method ‘showAction’ receives an instance of the model Posts, the developer could inspect this before dispatch the action preparing the parameter accordingly:

```
<?php

use Phalcon\Text;
use Phalcon\Mvc\Dispatcher as MvcDispatcher;
use Phalcon\Events\Manager as EventsManager;

$di->set('dispatcher', function() {

    //Create an EventsManager
    $eventsManager = new EventsManager();

    $eventsManager->attach("dispatch:beforeDispatchLoop", function($event, $dispatcher) {

        //Possible controller class name
        $controllerName = Text::camelize($dispatcher->getControllerName()) . 'Controller';

        //Possible method name
        $actionName = $dispatcher->getActionName() . 'Action';

        try {

            //Get the reflection for the method to be executed
            $reflection = new \ReflectionMethod($controllerName, $actionName);

            //Check parameters
            foreach ($reflection->getParameters() as $parameter) {

                //Get the expected model name
                $className = $parameter->getClass()->name;

                //Check if the parameter expects a model instance
                if (is_subclass_of($className, 'Phalcon\Mvc\Model')) {

                    $model = $className::findFirstById($dispatcher->getParams()[0]);

                    //Override the parameters by the model instance
                    $dispatcher->setParams(array($model));
                }
            }
        }
    });
});
```

```

        }

    } catch (\Exception $e) {
        //An exception has occurred, maybe the class or action does not exist?
    }

};

$dispatcher = new MvcDispatcher();
$dispatcher->setEventsManager($eventsManager);

return $dispatcher;
);
}

```

The above example has been simplified for academic purposes. A developer can improve it to inject any kind of dependency or model in actions before be executed.

2.23.6 Handling Not-Found Exceptions

Using the `EventManager` it's possible to insert a hook point before the dispatcher throws an exception when the controller/action combination wasn't found:

```

<?php

use Phalcon\Dispatcher;
use Phalcon\Mvc\Dispatcher as MvcDispatcher;
use Phalcon\Events\Manager as EventsManager;
use Phalcon\Mvc\Dispatcher\Exception as DispatchException;

$di->set('dispatcher', function() {

    //Create an EventsManager
    $eventsManager = new EventsManager();

    //Attach a listener
    $eventsManager->attach("dispatch:beforeException", function($event, $dispatcher, $exception) {

        //Handle 404 exceptions
        if ($exception instanceof DispatchException) {
            $dispatcher->forward(array(
                'controller' => 'index',
                'action'      => 'show404'
            ));
            return false;
        }

        //Alternative way, controller or action doesn't exist
        if ($event->getType() == 'beforeException') {
            switch ($exception->getCode()) {
                case \Phalcon\Dispatcher::EXCEPTION_HANDLER_NOT_FOUND:
                case \Phalcon\Dispatcher::EXCEPTION_ACTION_NOT_FOUND:
                    $dispatcher->forward(array(
                        'controller' => 'index',
                        'action'      => 'show404'
                    ));
                    return false;
            }
        }
    });
});

```

```
        }

    });

$dispatcher = new \Phalcon\Mvc\Dispatcher();

//Bind the EventsManager to the dispatcher
$dispatcher->setEventsManager($eventsManager);

return $dispatcher;

}, true);
```

Of course, this method can be moved onto independent plugin classes, allowing more than one class take actions when an exception is produced in the dispatch loop:

```
<?php

use Phalcon\Events\Event;
use Phalcon\Mvc\Dispatcher;
use Phalcon\Mvc\Dispatcher\Exception as DispatchException;

class ExceptionsPlugin
{
    public function beforeException(Event $event, Dispatcher $dispatcher, $exception)
    {

        //Handle 404 exceptions
        if ($exception instanceof DispatchException) {
            $dispatcher->forward(array(
                'controller' => 'index',
                'action'      => 'show404'
            ));
            return false;
        }

        //Handle other exceptions
        $dispatcher->forward(array(
            'controller' => 'index',
            'action'      => 'show503'
        ));

        return false;
    }
}
```

Only exceptions produced by the dispatcher and exceptions produced in the executed action are notified in the ‘beforeException’ events. Exceptions produced in listeners or controller events are redirected to the latest try/catch.

2.23.7 Implementing your own Dispatcher

The `Phalcon\Mvc\DispatcherInterface` interface must be implemented to create your own dispatcher replacing the one provided by Phalcon.

2.24 Micro Applications

With Phalcon you can create “Micro-Framework like” applications. By doing this, you only need to write a minimal amount of code to create a PHP application. Micro applications are suitable to implement small applications, APIs and prototypes in a practical way.

```
<?php

use Phalcon\Mvc\Micro;

$app = new Micro();

$app->get('/say/welcome/{name}', function ($name) {
    echo "<h1>Welcome $name!</h1>";
});

$app->handle();
```

2.24.1 Creating a Micro Application

`Phalcon\Mvc\Micro` is the class responsible for implementing a micro application.

```
<?php

use Phalcon\Mvc\Micro;

$app = new Micro();
```

2.24.2 Defining routes

After instantiating the object, you will need to add some routes. `Phalcon\Mvc\Router` manages routing internally. Routes must always start with `/`. A HTTP method constraint is optionally required when defining routes, so as to instruct the router to match only if the request also matches the HTTP methods. The following example shows how to define a route for the method GET:

```
<?php

$app->get('/say/hello/{name}', function ($name) {
    echo "<h1>Hello! $name</h1>";
});
```

The “get” method indicates that the associated HTTP method is GET. The route `/say/hello/{name}` also has a parameter `[$name]` that is passed directly to the route handler (the anonymous function). Handlers are executed when a route is matched. A handler could be any callable item in the PHP userland. The following example shows how to define different types of handlers:

```
<?php

// With a function
function say_hello($name) {
    echo "<h1>Hello! $name</h1>";
}

$app->get('/say/hello/{name}', "say_hello");
```

```
// With a static method
$app->get('/say/hello/{name}', "SomeClass::someSayMethod");

// With a method in an object
$myController = new MyController();
$app->get('/say/hello/{name}', array($myController, "someAction"));

//Anonymous function
$app->get('/say/hello/{name}', function ($name) {
    echo "<h1>Hello! $name</h1>";
});
```

Phalcon\Mvc\Micro provides a set of methods to define the HTTP method (or methods) which the route is constrained for:

```
<?php

//Matches if the HTTP method is GET
$app->get('/api/products', "get_products");

//Matches if the HTTP method is POST
$app->post('/api/products/add', "add_product");

//Matches if the HTTP method is PUT
$app->put('/api/products/update/{id}', "update_product");

//Matches if the HTTP method is DELETE
$app->delete('/api/products/remove/{id}', "delete_product");

//Matches if the HTTP method is OPTIONS
$app->options('/api/products/info/{id}', "info_product");

//Matches if the HTTP method is PATCH
$app->patch('/api/products/update/{id}', "info_product");

//Matches if the HTTP method is GET or POST
$app->map('/repos/store/refs', "action_product")->via(array('GET', 'POST'));
```

Routes with Parameters

Defining parameters in routes is very easy as demonstrated above. The name of the parameter has to be enclosed in brackets. Parameter formatting is also available using regular expressions to ensure consistency of data. This is demonstrated in the example below:

```
<?php

//This route have two parameters and each of them have a format
$app->get('/posts/{year:[0-9]+}/{title:[a-zA-Z\-\-]+}', function ($year, $title) {
    echo "<h1>Title: $title</h1>";
    echo "<h2>Year: $year</h2>";
});
```

Starting Route

Normally, the starting route in an application is the route /, and it will more frequent to be accessed by the method GET. This scenario is coded as follows:

```
<?php

// This is the start route
$app->get('/', function () {
    echo "<h1>Welcome!</h1>";
});
```

Rewrite Rules

The following rules can be used together with Apache to rewrite the URIs:

```
<IfModule mod_rewrite.c>
    RewriteEngine On
    RewriteCond %{REQUEST_FILENAME} !-f
    RewriteRule ^(.*)$ index.php?url=/\$1 [QSA,L]
</IfModule>
```

2.24.3 Working with Responses

You are free to produce any kind of response in a handler: directly make an output, use a template engine, include a view, return a json, etc.:

```
<?php

// Direct output
$app->get('/say/hello', function () {
    echo "<h1>Hello! $name</h1>";
});

// Requiring another file
$app->get('/show/results', function () {
    require 'views/results.php';
});

// Returning a JSON
$app->get('/get/some-json', function () {
    echo json_encode(array("some", "important", "data"));
});
```

In addition to that, you have access to the service “response”, with which you can manipulate better the response:

```
<?php

$app->get('/show/data', function () use ($app) {

    //Set the Content-Type header
    $app->response->setContentType('text/plain')->sendHeaders();

    //Print a file
    readfile("data.txt");

});
```

Or create a response object and return it from the handler:

```
<?php

$app->get('/show/data', function () {

    // Create a response
    $response = new Phalcon\Http\Response();

    // Set the Content-Type header
    $response->setContentType('text/plain');

    // Pass the content of a file
    $response->setContent(file_get_contents("data.txt"));

    // Return the response
    return $response;
});
```

2.24.4 Making redirections

Redirections could be performed to forward the execution flow to another route:

```
<?php

// This route makes a redirection to another route
$app->post('/old/welcome', function () use ($app) {
    $app->response->redirect("new/welcome")->sendHeaders();
});

$app->post('/new/welcome', function () use ($app) {
    echo 'This is the new Welcome';
});
```

2.24.5 Generating URLs for Routes

Phalcon\Mvc\Url can be used to produce URLs based on the defined routes. You need to set up a name for the route; by this way the “url” service can produce the corresponding URL:

```
<?php

// Set a route with the name "show-post"
$app->get('/blog/{year}/{title}', function ($year, $title) use ($app) {
    //.. show the post here
})->setName('show-post');

// produce an URL somewhere
$app->get('/', function() use ($app) {

    echo '<a href=""', $app->url->get(array(
        'for' => 'show-post',
        'title' => 'php-is-a-great-framework',
        'year' => 2015
    )), '">Show the post</a>';

});
```

2.24.6 Interacting with the Dependency Injector

In the micro application, a `Phalcon\DI\FactoryDefault` services container is created implicitly; additionally you can create outside the application a container to manipulate its services:

```
<?php

use Phalcon\Mvc\Micro;
use Phalcon\DI\FactoryDefault;
use Phalcon\Config\Adapter\Ini as IniConfig;

$di = new FactoryDefault();

$di->set('config', function() {
    return new IniConfig("config.ini");
});

$app = new Micro();

$app->setDI($di);

$app->get('/', function () use ($app) {
    //Read a setting from the config
    echo $app->config->app_name;
});

$app->post('/contact', function () use ($app) {
    $app->flash->success('Yes!, the contact was made!');
});
```

The array-syntax is allowed to easily set/get services in the internal services container:

```
<?php

use Phalcon\Mvc\Micro;
use Phalcon\Db\Adapter\Pdo\Mysql as MysqlAdapter;

$app = new Micro();

// Setup the database service
$app['db'] = function() {
    return new MysqlAdapter(array(
        "host"      => "localhost",
        "username"  => "root",
        "password"  => "secret",
        "dbname"    => "test_db"
    ));
};

$app->get('/blog', function () use ($app) {
    $news = $app['db']->query('SELECT * FROM news');
    foreach ($news as $new) {
        echo $new->title;
    }
});
```

2.24.7 Not-Found Handler

When an user tries to access a route that is not defined, the micro application will try to execute the “Not-Found” handler. An example of that behavior is below:

```
<?php

$app->notFound(function () use ($app) {
    $app->response->setStatusCode(404, "Not Found")->sendHeaders();
    echo 'This is crazy, but this page was not found!';
});
```

2.24.8 Models in Micro Applications

Models can be used transparently in Micro Applications, only is required an autoloader to load models:

```
<?php

$loader = new \Phalcon\Loader();

$loader->registerDirs(array(
    __DIR__ . '/models/'
))->register();

$app = new \Phalcon\Mvc\Micro();

$app->get('/products/find', function() {

    foreach (Products::find() as $product) {
        echo $product->name, '<br>';
    }
});

$app->handle();
```

2.24.9 Micro Application Events

`\Phalcon\Mvc\Micro` is able to send events to the `EventsManager` (if it is present). Events are triggered using the type “micro”. The following events are supported:

Event Name	Triggered	Can stop operation?
beforeHandleRoute	The main method is just called, at this point the application doesn't know if there is some matched route	Yes
beforeExecuteRoute	A route has been matched and it contains a valid handler, at this point the handler has not been executed	Yes
afterExecuteRoute	Triggered after running the handler	No
beforeNotFound	Triggered when any of the defined routes match the requested URI	Yes
afterHandleRoute	Triggered after completing the whole process in a successful way	Yes

In the following example, we explain how to control the application security using events:

```
<?php

use Phalcon\Mvc\Micro,
    Phalcon\Events\Manager as EventsManager;

// Create a events manager
$eventManager = new EventsManager();

// Listen all the application events
$eventManager->attach('micro', function($event, $app) {

    if ($event->getType() == 'beforeExecuteRoute') {
        if ($app->session->get('auth') == false) {

            $app->flashSession->error("The user isn't authenticated");
            $app->response->redirect ("/")->sendHeaders();

            //Return (false) stop the operation
            return false;
        }
    }
});

$app = new Micro();

// Bind the events manager to the app
$app->setEventsManager($eventManager);
```

2.24.10 Middleware events

In addition to the events manager, events can be added using the methods ‘before’, ‘after’ and ‘finish’:

```
<?php

$app = new Phalcon\Mvc\Micro();

// Executed before every route is executed
// Return false cancels the route execution
$app->before(function() use ($app) {
    if ($app['session']->get('auth') == false) {
        return false;
    }
    return true;
});

$app->map('/api/robots', function() {
    return array(
        'status' => 'OK'
    );
});

$app->after(function() use ($app) {
    // This is executed after the route was executed
    echo json_encode($app->getReturnedValue());
});
```

```
$app->finish(function() use ($app) {
    // This is executed when the request has been served
});
```

You can call the methods several times to add more events of the same type:

```
<?php

$app->finish(function() use ($app) {
    // First 'finish' middleware
});

$app->finish(function() use ($app) {
    // Second 'finish' middleware
});
```

Code for middlewares can be reused using separate classes:

```
<?php

use Phalcon\Mvc\Micro\MiddlewareInterface;

/**
 * CacheMiddleware
 *
 * Caches pages to reduce processing
 */
class CacheMiddleware implements MiddlewareInterface
{
    public function call($application)
    {

        $cache = $application['cache'];
        $router = $application['router'];

        $key = preg_replace('/^/[a-zA-Z0-9]/', '', $router->getRewriteUri());

        // Check if the request is cached
        if ($cache->exists($key)) {
            echo $cache->get($key);
            return false;
        }

        return true;
    }
}
```

Then add the instance to the application:

```
<?php

$app->before(new CacheMiddleware());
```

The following middleware events are available:

Event Name	Triggered	Can stop operation?
before	Before executing the handler. It can be used to control the access to the application	Yes
after	Executed after the handler is executed. It can be used to prepare the response	No
finish	Executed after sending the response. It can be used to perform clean-up	No

2.24.11 Using Controllers as Handlers

Medium applications using the Micro\mvc approach may require organize handlers in controllers. You can use `Phalcon\mvc\micro\Collection` to group handlers that belongs to controllers:

```
<?php

use Phalcon\Mvc\Micro\Collection as MicroCollection;

$posts = new MicroCollection();

//Set the main handler. ie. a controller instance
$posts->setHandler(new PostsController());

//Set a common prefix for all routes
$posts->setPrefix('/posts');

//Use the method 'index' in PostsController
$posts->get('/', 'index');

//Use the method 'show' in PostsController
$posts->get('/show/{slug}', 'show');

$app->mount($posts);
```

The controller ‘PostsController’ might look like this:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function index()
    {
        //...
    }

    public function show($slug)
    {
        //...
    }
}
```

In the above example the controller is directly instantiated, Collection also have the ability to lazy-load controllers, this option provide better performance loading controllers only if the related routes are matched:

```
<?php

$posts->setHandler('PostsController', true);
$posts->setHandler('Blog\Controllers\PostsController', true);
```

2.24.12 Returning Responses

Handlers may return raw responses using `Phalcon\Http\Response` or a component that implements the relevant interface. When responses are returned by handlers they are automatically sent by the application.

```
<?php

use Phalcon\Mvc\Micro;
use Phalcon\Http\Response;

$app = new Micro();

// Return a response
$app->get('/welcome/index', function() {

    $response = new Response();

    $response->setStatusCode(401, "Unauthorized");

    $response->setContent("Access is not authorized");

    return $response;
});
```

2.24.13 Rendering Views

`Phalcon\Mvc\View\Simple` can be used to render views, the following example shows how to do that:

```
<?php

$app = new Phalcon\Mvc\Micro();

$app['view'] = function() {
    $view = new \Phalcon\Mvc\View\Simple();
    $view->setViewsDir('app/views/');
    return $view;
};

//Return a rendered view
$app->get('/products/show', function() use ($app) {

    // Render app/views/products/show.phtml passing some variables
    echo $app['view']->render('products/show', array(
        'id' => 100,
        'name' => 'Artichoke'
    ));
});
```

2.24.14 Error Handling

A proper response can be generated if an exception is raised in a micro handler:

```
<?php

$app = new Phalcon\Mvc\Micro();

$app->get('/', function() {
    throw new \Exception("An error");
});

$app->error(function($exception) {
    echo "An error has occurred";
});
```

If the handler returns “false” the exception is stopped.

- [Creating a Simple REST API](#) is a tutorial that explains how to create a micro application to implement a RESTful web service.
- [Stickers Store](#) is a very simple micro-application making use of the micro-mvc approach [[Github](#)].

2.25 Working with Namespaces

[Namespaces](#) can be used to avoid class name collisions; this means that if you have two controllers in an application with the same name, a namespace can be used to differentiate them. Namespaces are also useful for creating bundles or modules.

2.25.1 Setting up the framework

Using namespaces has some implications when loading the appropriate controller. To adjust the framework behavior to namespaces is necessary to perform one or all of the following tasks:

Use an autoload strategy that takes into account the namespaces, for example with `Phalcon\Loader`:

```
<?php

$loader->registerNamespaces(
    array(
        'Store\Admin\Controllers' => '../bundles/admin/controllers/',
        'Store\Admin\Models'       => '../bundles/admin/models/',
    )
);
```

Specify it in the routes as a separate parameter in the route’s paths:

```
<?php

$router->add(
    '/admin/users/my-profile',
    array(
        'namespace' => 'Store\Admin',
    )
);
```

```
    'controller' => 'Users',
    'action'      => 'profile',
)
);
```

Passing it as part of the route:

```
<?php

$router->add(
    '/:namespace/admin/users/my-profile',
    array(
        'namespace'  => 1,
        'controller' => 'Users',
        'action'      => 'profile',
    )
);
```

If you are only working with the same namespace for every controller in your application, then you can define a default namespace in the Dispatcher, by doing this, you don't need to specify a full class name in the router path:

```
<?php

use Phalcon\Mvc\Dispatcher;

// Registering a dispatcher
$di->set('dispatcher', function() {
    $dispatcher = new Dispatcher();
    $dispatcher->setDefaultNamespace('Store\Admin\Controllers');
    return $dispatcher;
});
```

2.25.2 Controllers in Namespaces

The following example shows how to implement a controller that use namespaces:

```
<?php

namespace Store\Admin\Controllers;

use Phalcon\Mvc\Controller;

class UsersController extends Controller
{

    public function indexAction()
    {

    }

    public function profileAction()
    {

    }
}
```

2.25.3 Models in Namespaces

Take the following into consideration when using models in namespaces:

```
<?php

namespace Store\Models;

use Phalcon\Mvc\Model;

class Robots extends Model
{}
```

If models have relationships they must include the namespace too:

```
<?php

namespace Store\Models;

use Phalcon\Mvc\Model;

class Robots extends Model
{
    public function initialize()
    {
        $this->hasMany('id', 'Store\Models\Parts', 'robots_id', array(
            'alias' => 'parts'
        ));
    }
}
```

In PHQL you must write the statements including namespaces:

```
<?php

$phql = 'SELECT r.* FROM Store\Models\Robots r JOIN Store\Models\Parts p';
```

2.26 Events Manager

The purpose of this component is to intercept the execution of most of the components of the framework by creating “hooks point”. These hook points allow the developer to obtain status information, manipulate data or change the flow of execution during the process of a component.

2.26.1 Usage Example

In the following example, we use the EventsManager to listen for events produced in a MySQL connection managed by Phalcon\Db. First, we need a listener object to do this. We created a class whose methods are the events we want to listen:

```
<?php

class MyDbListener
{
```

```
public function afterConnect()
{
}

public function beforeQuery()
{
}

public function afterQuery()
{
}

}
```

This new class can be as verbose as we need it to. The EventsManager will interface between the component and our listener class, offering hook points based on the methods we defined in our listener class:

```
<?php

use Phalcon\Events\Manager as EventsManager;
use Phalcon\Db\Adapter\Pdo\Mysql as DbAdapter;

$eventsManager = new EventsManager();

//Create a database listener
$dbListener     = new MyDbListener();

//Listen all the database events
$eventsManager->attach('db', $dbListener);

$connection     = new DbAdapter(array(
    "host"        => "localhost",
    "username"    => "root",
    "password"    => "secret",
    "dbname"      => "invo"
));

//Assign the eventsManager to the db adapter instance
$connection->setEventsManager($eventsManager);

//Send a SQL command to the database server
$connection->query("SELECT * FROM products p WHERE p.status = 1");
```

In order to log all the SQL statements executed by our application, we need to use the event “afterQuery”. The first parameter passed to the event listener contains contextual information about the event that is running, the second is the connection itself.

```
<?php

use Phalcon\Logger\Adapter\File as Logger;

class MyDbListener
{

    protected $_logger;
```

```

public function __construct()
{
    $this->_logger = new Logger("../apps/logs/db.log");
}

public function afterQuery($event, $connection)
{
    $this->_logger->log($connection->getSQLStatement(), \Phalcon\Logger::INFO);
}

}

```

As part of this example, we will also implement the Phalcon\Db\Profiler to detect the SQL statements that are taking longer to execute than expected:

```

<?php

use Phalcon\Db\Profiler;
use Phalcon\Logger;
use Phalcon\Logger\Adapter\File;

class MyDbListener
{

    protected $_profiler;

    protected $_logger;

    /**
     * Creates the profiler and starts the logging
     */
    public function __construct()
    {
        $this->_profiler = new Profiler();
        $this->_logger = new Logger("../apps/logs/db.log");
    }

    /**
     * This is executed if the event triggered is 'beforeQuery'
     */
    public function beforeQuery($event, $connection)
    {
        $this->_profiler->startProfile($connection->getSQLStatement());
    }

    /**
     * This is executed if the event triggered is 'afterQuery'
     */
    public function afterQuery($event, $connection)
    {
        $this->_logger->log($connection->getSQLStatement(), Logger::INFO);
        $this->_profiler->stopProfile();
    }

    public function getProfiler()
    {
        return $this->_profiler;
    }
}

```

```
}
```

The resulting profile data can be obtained from the listener:

```
<?php

//Send a SQL command to the database server
$connection->execute("SELECT * FROM products p WHERE p.status = 1");

foreach ($dbListener->getProfiler()->getProfiles() as $profile) {
    echo "SQL Statement: ", $profile->getSQLStatement(), "\n";
    echo "Start Time: ", $profile->getInitialTime(), "\n";
    echo "Final Time: ", $profile->getFinalTime(), "\n";
    echo "Total Elapsed Time: ", $profile->getTotalElapsedSeconds(), "\n";
}
```

In a similar manner we can register an lambda function to perform the task instead of a separate listener class (as seen above):

```
<?php

//Listen all the database events
$eventManager->attach('db', function($event, $connection) {
    if ($event->getType() == 'afterQuery') {
        echo $connection->getSQLStatement();
    }
});
```

2.26.2 Creating components that trigger Events

You can create components in your application that trigger events to an EventsManager. As a consequence, there may exist listeners that react to these events when generated. In the following example we're creating a component called "MyComponent". This component is EventsManager aware; when its method "someTask" is executed it triggers two events to any listener in the EventsManager:

```
<?php

use Phalcon\Events\EventsAwareInterface;

class MyComponent implements EventsAwareInterface
{

    protected $_eventsManager;

    public function setEventsManager($eventsManager)
    {
        $this->_eventsManager = $eventsManager;
    }

    public function getEventsManager()
    {
        return $this->_eventsManager;
    }

    public function someTask()
    {
        $this->_eventsManager->fire("my-component:beforeSomeTask", $this);
```

```
// do some task

$this->_eventsManager->fire("my-component:afterSomeTask", $this);
}

}
```

Note that events produced by this component are prefixed with “my-component”. This is a unique word that helps us identify events that are generated from certain component. You can even generate events outside the component with the same name. Now let’s create a listener to this component:

```
<?php

class SomeListener
{

    public function beforeSomeTask($event, $myComponent)
    {
        echo "Here, beforeSomeTask\n";
    }

    public function afterSomeTask($event, $myComponent)
    {
        echo "Here, afterSomeTask\n";
    }
}
```

A listener is simply a class that implements any of all the events triggered by the component. Now let’s make everything work together:

```
<?php

use Phalcon\Events\Manager as EventsManager;

//Create an Events Manager
$eventsManager = new EventsManager();

//Create the MyComponent instance
$myComponent = new MyComponent();

//Bind the eventsManager to the instance
$myComponent->setEventsManager($eventsManager);

//Attach the listener to the EventsManager
$eventsManager->attach('my-component', new SomeListener());

//Execute methods in the component
$myComponent->someTask();
```

As “someTask” is executed, the two methods in the listener will be executed, producing the following output:

```
Here, beforeSomeTask
Here, afterSomeTask
```

Additional data may also passed when triggering an event using the third parameter of “fire”:

```
<?php
```

```
$eventsManager->fire("my-component:afterSomeTask", $this, $extraData);
```

In a listener the third parameter also receives this data:

```
<?php

//Receiving the data in the third parameter
$eventManager->attach('my-component', function($event, $component, $data) {
    print_r($data);
});

//Receiving the data from the event context
$eventManager->attach('my-component', function($event, $component) {
    print_r($event->getData());
});
```

If a listener it is only interested in listening a specific type of event you can attach a listener directly:

```
<?php

//The handler will only be executed if the event triggered is "beforeSomeTask"
$eventManager->attach('my-component:beforeSomeTask', function($event, $component) {
    //...
});
```

2.26.3 Event Propagation/Cancellation

Many listeners may be added to the same event manager, this means that for the same type of event many listeners can be notified. The listeners are notified in the order they were registered in the EventsManager. Some events are cancelable, indicating that these may be stopped preventing other listeners are notified about the event:

```
<?php

$eventsManager->attach('db', function($event, $connection) {

    //We stop the event if it is cancelable
    if ($event->isCancelable()) {
        //Stop the event, so other listeners will not be notified about this
        $event->stop();
    }

    //...
});
```

By default events are cancelable, even most of events produced by the framework are cancelables. You can fire a not-cancelable event by passing “false” in the fourth parameter of fire:

```
<?php

$eventsManager->fire("my-component:afterSomeTask", $this, $extraData, false);
```

2.26.4 Listener Priorities

When attaching listeners you can set a specific priority. With this feature you can attach listeners indicating the order in which they must be called:

```
<?php

$evManager->enablePriorities(true);

$evManager->attach('db', new DbListener(), 150); //More priority
$evManager->attach('db', new DbListener(), 100); //Normal priority
$evManager->attach('db', new DbListener(), 50); //Less priority
```

2.26.5 Collecting Responses

The events manager can collect every response returned by every notified listener, this example explains how it works:

```
<?php

use Phalcon\Events\Manager as EventsManager;

$evManager = new EventsManager();

//Set up the events manager to collect responses
$evManager->collectResponses(true);

//Attach a listener
$evManager->attach('custom:custom', function() {
    return 'first response';
});

//Attach a listener
$evManager->attach('custom:custom', function() {
    return 'second response';
});

//Fire the event
$evManager->fire('custom:custom', null);

//Get all the collected responses
print_r($evManager->getResponses());
```

The above example produces:

```
Array ( [0] => first response [1] => second response )
```

2.26.6 Implementing your own EventsManager

The `Phalcon\Events\ManagerInterface` interface must be implemented to create your own `EventsManager` replacing the one provided by Phalcon.

2.27 Request Environment

Every HTTP request (usually originated by a browser) contains additional information regarding the request such as header data, files, variables, etc. A web based application needs to parse that information so as to provide the correct response back to the requester. `Phalcon\Http\Request` encapsulates the information of the request, allowing you to access it in an object-oriented way.

```
<?php

use Phalcon\Http\Request;

// Getting a request instance
$request = new Request();

// Check whether the request was made with method POST
if ($request->isPost() == true) {

    // Check whether the request was made with Ajax
    if ($request->isAjax() == true) {
        echo "Request was made using POST and AJAX";
    }
}
```

2.27.1 Getting Values

PHP automatically fills the superglobal arrays `$_GET` and `$_POST` depending on the type of the request. These arrays contain the values present in forms submitted or the parameters sent via the URL. The variables in the arrays are never sanitized and can contain illegal characters or even malicious code, which can lead to [SQL injection](#) or [Cross Site Scripting \(XSS\)](#) attacks.

`Phalcon\Http\Request` allows you to access the values stored in the `$_REQUEST`, `$_GET` and `$_POST` arrays and sanitize or filter them with the ‘filter’ service, (by default `Phalcon\Filter`). The following examples offer the same behavior:

```
<?php

use Phalcon\Filter;

// Manually applying the filter
$filter = new Filter();
$email = $filter->sanitize($_POST["user_email"], "email");

// Manually applying the filter to the value
$filter = new Filter();
$email = $filter->sanitize($request->getPost("user_email"), "email");

// Automatically applying the filter
$email = $request->getPost("user_email", "email");

// Setting a default value if the param is null
$email = $request->getPost("user_email", "email", "some@example.com");

// Setting a default value if the param is null without filtering
$email = $request->getPost("user_email", null, "some@example.com");
```

2.27.2 Accessing the Request from Controllers

The most common place to access the request environment is in an action of a controller. To access the `Phalcon\Http\Request` object from a controller you will need to use the `$this->request` public property of the controller:

```
<?php
```

```
use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function saveAction()
    {

        // Check if request has made with POST
        if ($this->request->isPost() == true) {

            // Access POST data
            $customerName = $this->request->getPost("name");
            $customerBorn = $this->request->getPost("born");

        }

    }

}
```

2.27.3 Uploading Files

Another common task is file uploading. [Phalcon\Http\Request](#) offers an object-oriented way to achieve this task:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function uploadAction()
    {
        // Check if the user has uploaded files
        if ($this->request->hasFiles() == true) {

            // Print the real file names and sizes
            foreach ($this->request->getUploadedFiles() as $file) {

                //Print file details
                echo $file->getName(), " ", $file->getSize(), "\n";

                //Move the file into the application
                $file->moveTo('files/' . $file->getName());
            }
        }
    }
}
```

Each object returned by [Phalcon\Http\Request::getUploadedFiles\(\)](#) is an instance of the [Phalcon\Http\Request\File](#)

class. Using the `$_FILES` superglobal array offers the same behavior. `Phalcon\Http\Request\File` encapsulates only the information related to each file uploaded with the request.

2.27.4 Working with Headers

As mentioned above, request headers contain useful information that allow us to send the proper response back to the user. The following examples show usages of that information:

```
<?php

// get the Http-X-Requested-With header
$requestWith = $request->getHeader("HTTP_X_REQUESTED_WITH");
if ($requestWith == "XMLHttpRequest") {
    echo "The request was made with Ajax";
}

// Same as above
if ($request->isAjax()) {
    echo "The request was made with Ajax";
}

// Check the request layer
if ($request->isSecureRequest() == true) {
    echo "The request was made using a secure layer";
}

// Get the servers's ip address. ie. 192.168.0.100
$ipAddress = $request->getServerAddress();

// Get the client's ip address ie. 201.245.53.51
$ipAddress = $request->getClientAddress();

// Get the User Agent (HTTP_USER_AGENT)
$userAgent = $request->getUserAgent();

// Get the best acceptable content by the browser. ie text/xml
$contentType = $request->getAcceptableContent();

// Get the best charset accepted by the browser. ie. utf-8
$charset = $request->getBestCharset();

// Get the best language accepted configured in the browser. ie. en-us
$language = $request->getBestLanguage();
```

2.28 Returning Responses

Part of the HTTP cycle is returning responses to clients. `Phalcon\Http\Response` is the Phalcon component designed to achieve this task. HTTP responses are usually composed by headers and body. The following is an example of basic usage:

```
<?php

use Phalcon\Http\Response;

//Getting a response instance
```

```
$response = new Response();

//Set status code
$response->setStatusCode(404, "Not Found");

//Set the content of the response
$response->setContent("Sorry, the page doesn't exist");

//Send response to the client
$response->send();
```

If you are using the full MVC stack there is no need to create responses manually. However, if you need to return a response directly from a controller's action follow this example:

```
<?php

use Phalcon\Http\Response;
use Phalcon\Mvc\Controller;

class FeedController extends Controller
{

    public function getAction()
    {
        // Getting a response instance
        $response = new Response();

        $feed      = //... load here the feed

        //Set the content of the response
        $response->setContent($feed->asString());

        //Return the response
        return $response;
    }
}
```

2.28.1 Working with Headers

Headers are an important part of the HTTP response. It contains useful information about the response state like the HTTP status, type of response and much more.

You can set headers in the following way:

```
<?php

//Setting a header by it's name
$response->setHeader("Content-Type", "application/pdf");
$response->setHeader("Content-Disposition", 'attachment; filename="downloaded.pdf"');

//Setting a raw header
$response->setRawHeader("HTTP/1.1 200 OK");
```

A `Phalcon\Http\Response\Headers` bag internally manages headers. This class retrieves the headers before sending it to client:

```
<?php

//Get the headers bag
$headers = $response->getHeaders();

//Get a header by its name
$contentType = $response->getHeaders()->get("Content-Type");
```

2.28.2 Making Redirections

With Phalcon\Http\Response you can also execute HTTP redirections:

```
<?php

//Redirect to the default URI
$response->redirect();

//Redirect to the local base URI
$response->redirect("posts/index");

//Redirect to an external URL
$response->redirect("http://en.wikipedia.org", true);

//Redirect specifying the HTTP status code
$response->redirect("http://www.example.com/new-location", true, 301);
```

All internal URIs are generated using the ‘url’ service (by default Phalcon\Mvc\Url). This example demonstrates how you can redirect using a route you have defined in your application:

```
<?php

//Redirect based on a named route
return $response->redirect(array(
    "for"      => "index-lang",
    "lang"     => "jp",
    "controller" => "index"
));
```

Note that a redirection doesn’t disable the view component, so if there is a view associated with the current action it will be executed anyway. You can disable the view from a controller by executing \$this->view->disable();

2.28.3 HTTP Cache

One of the easiest ways to improve the performance in your applications and reduce the server traffic is using HTTP Cache. Most modern browsers support HTTP caching. HTTP Cache is one of the reasons many websites are currently fast.

HTTP Cache can be altered in the following header values sent by the application when serving a page for the first time:

- *Expires*: With this header the application can set a date in the future or the past telling the browser when the page must expire.
- *Cache-Control*: This header allows to specify how much time a page should be considered fresh in the browser.
- *Last-Modified*: This header tells the browser which was the last time the site was updated avoiding page re-loads

- *ETag*: An etag is a unique identifier that must be created including the modification timestamp of the current page

Setting an Expiration Time

The expiration date is one of the easiest and most effective ways to cache a page in the client (browser). Starting from the current date we add the amount of time the page will be stored in the browser cache. Until this date expires no new content will be requested from the server:

```
<?php

$expireDate = new DateTime();
$expireDate->modify('+2 months');

$response->setExpires($expireDate);
```

The Response component automatically shows the date in GMT timezone as expected in an Expires header.

If we set this value to a date in the past the browser will always refresh the requested page:

```
<?php

$expireDate = new DateTime();
$expireDate->modify('-10 minutes');

$response->setExpires($expireDate);
```

Browsers rely on the client's clock to assess if this date has passed or not. The client clock can be modified to make pages expire and this may represent a limitation for this cache mechanism.

Cache-Control

This header provides a safer way to cache the pages served. We simply must specify a time in seconds telling the browser how long it must keep the page in its cache:

```
<?php

//Starting from now, cache the page for one day
$response->setHeader('Cache-Control', 'max-age=86400');
```

The opposite effect (avoid page caching) is achieved in this way:

```
<?php

//Never cache the served page
$response->setHeader('Cache-Control', 'private, max-age=0, must-revalidate');
```

E-Tag

An “entity-tag” or “E-tag” is a unique identifier that helps the browser realize if the page has changed or not between two requests. The identifier must be calculated taking into account that this must change if the previously served content has changed:

```
<?php

//Calculate the E-Tag based on the modification time of the latest news
```

```
$recentDate = News::maximum(array('column' => 'created_at'));  
$eTag = md5($recentDate);  
  
//Send an E-Tag header  
$response->setHeader('E-Tag', $eTag);
```

2.29 Cookies Management

Cookies are very useful way to store small pieces of data in the client that can be retrieved even if the user closes his/her browser. Phalcon\Http\Response\Cookies acts as a global bag for cookies. Cookies are stored in this bag during the request execution and are sent automatically at the end of the request.

2.29.1 Basic Usage

You can set/get cookies by just accessing the ‘cookies’ service in any part of the application where services can be accessed:

```
<?php  
  
use Phalcon\Mvc\Controller;  
  
class SessionController extends Controller  
{  
    public function loginAction()  
    {  
        // Check if the cookie has previously set  
        if ($this->cookies->has('remember-me')) {  
  
            // Get the cookie  
            $rememberMe = $this->cookies->get('remember-me');  
  
            // Get the cookie's value  
            $value      = $rememberMe->getValue();  
  
        }  
    }  
  
    public function startAction()  
    {  
        $this->cookies->set('remember-me', 'some value', time() + 15 * 86400);  
    }  
}
```

2.29.2 Encryption/Decryption of Cookies

By default, cookies are automatically encrypted before be sent to the client and decrypted when retrieved. This protection allow unauthorized users to see the cookies’ contents in the client (browser). Although this protection, sensitive data should not be stored on cookies.

You can disable encryption in the following way:

```
<?php
```

```
use Phalcon\Http\Response\Cookies;

$di->set('cookies', function() {
    $cookies = new Cookies();
    $cookies->useEncryption(false);
    return $cookies;
});
```

In case of using encryption a global key must be set in the ‘crypt’ service:

```
<?php

use Phalcon\Crypt;

$di->set('crypt', function() {
    $crypt = new Crypt();
    $crypt->setKey('#1dj8$=dp?.ak//j1v$'); // Use your own key!
    return $crypt;
});
```

Send cookies data without encryption to clients including complex objects structures, resultsets, service information, etc. could expose internal application details that could be used by an attacker to attack the application. If you do not want to use encryption, we highly recommend you only send very basic cookie data like numbers or small string literals.

2.30 Generating URLs and Paths

Phalcon\Mvc\Url is the component responsible of generate urls in a Phalcon application. It’s capable of produce independent urls based on routes.

2.30.1 Setting a base URI

Depending of which directory of your document root your application is installed, it may have a base uri or not.

For example, if your document root is /var/www/htdocs and your application is installed in /var/www/htdocs/invo then your baseUri will be /invo/. If you are using a VirtualHost or your application is installed on the document root, then your baseUri is /. Execute the following code to know the base uri detected by Phalcon:

```
<?php

use Phalcon\Mvc\Url;

$url = new Url();
echo $url->getBaseUri();
```

By default, Phalcon automatically may detect your baseUri, but if you want to increase the performance of your application is recommended setting up it manually:

```
<?php

use Phalcon\Mvc\Url;

$url = new Url();

//Setting a relative base URI
```

```
$url->setBaseUri('/invo/');

//Setting a full domain as base URI
$url->setBaseUri('://my.domain.com/');

//Setting a full domain as base URI
$url->setBaseUri('http://my.domain.com/my-app/');
```

Usually, this component must be registered in the Dependency Injector container, so you can set up it there:

```
<?php

use Phalcon\Mvc\Url;

$di->set('url', function() {
    $url = new Url();
    $url->setBaseUri('/invo/');
    return $url;
});
```

2.30.2 Generating URIs

If you are using the [Router](#) with its default behavior. Your application is able to match routes based on the following pattern: `/:controller/:action/:params`. Accordingly it is easy to create routes that satisfy that pattern (or any other pattern defined in the router) passing a string to the method “get”:

```
<?php echo $url->get("products/save") ?>
```

Note that isn’t necessary to prepend the base uri. If you have named routes you can easily change it creating it dynamically. For Example if you have the following route:

```
<?php

$route->add('/blog/{year}/{month}/{title}', array(
    'controller' => 'posts',
    'action'      => 'show'
))->setName('show-post');
```

A URL can be generated in the following way:

```
<?php

//This produces: /blog/2012/01/some-blog-post
$url->get(array(
    'for'    => 'show-post',
    'year'   => 2012,
    'month'  => '01',
    'title'  => 'some-blog-post'
));
```

2.30.3 Producing URLs without Mod-Rewrite

You can use this component also to create urls without mod-rewrite:

```
<?php
```

```
use Phalcon\Mvc\Url;

$url = new Url();

//Pass the URI in $_GET["_url"]
$url->setBaseUri('/invo/index.php?_url=/');

//This produce: /invo/index.php?_url=/products/save
echo $url->get("products/save");
```

You can also use `$_SERVER["REQUEST_URI"]`:

```
<?php

use Phalcon\Mvc\Url;

$url = new Url();

//Pass the URI in $_GET["_url"]
$url->setBaseUri('/invo/index.php?_url=/');

//Pass the URI using $_SERVER["REQUEST_URI"]
$url->setBaseUri('/invo/index.php/');
```

In this case, it's necessary to manually handle the required URI in the Router:

```
<?php

use Phalcon\Mvc\Router;

$router = new Router();

// ... define routes

$uri = str_replace($_SERVER["SCRIPT_NAME"], '', $_SERVER["REQUEST_URI"]);
$router->handle($uri);
```

The produced routes would look like:

```
<?php

//This produce: /invo/index.php/products/save
echo $url->get("products/save");
```

2.30.4 Producing URLs from Volt

The function “url” is available in volt to generate URLs using this component:

```
<a href="{{ url('posts/edit/1002') }}">Edit</a>
```

Generate static routes:

```
<link rel="stylesheet" href="{{ static_url('css/style.css') }}" type="text/css" />
```

2.30.5 Static vs. Dynamic Uris

This component allow you to set up a different base uri for static resources in the application:

```
<?php

use Phalcon\Mvc\Url;

$url = new Url();

//Dynamic URIs are
$url->setBaseUri('/');

//Static resources go through a CDN
$url->setStaticBaseUri('http://static.mywebsite.com/');
```

Phalcon\Tag will request both dynamical and static URIs using this component.

2.30.6 Implementing your own Url Generator

The `Phalcon\Mvc\UrlInterface` interface must be implemented to create your own URL generator replacing the one provided by Phalcon.

2.31 Flashing Messages

Flash messages are used to notify the user about the state of actions he/she made or simply show information to the users. These kind of messages can be generated using this component.

2.31.1 Adapters

This component makes use of adapters to define the behavior of the messages after being passed to the Flasher:

Adapter	Description	API
Direct	Directly outputs the messages passed to the flasher	<code>Phalcon\Flash\Direct</code>
Session	Temporarily stores the messages in session, then messages can be printed in the next request	<code>Phalcon\Flash\Session</code>

2.31.2 Usage

Usually the Flash Messaging service is requested from the services container, if you're using `Phalcon\DI\FactoryDefault` then `Phalcon\Flash\Direct` is automatically registered as "flash" service:

```
<?php

use Phalcon\Flash\Direct as FlashDirect;

// Set up the flash service
$di->set('flash', function() {
    return new FlashDirect();
});
```

This way, you can use it in controllers or views by injecting the service in the required scope:

```
<?php

use Phalcon\Mvc\Controller;

class PostsController extends Controller
{

    public function indexAction()
    {

    }

    public function saveAction()
    {
        $this->flash->success("The post was correctly saved!");
    }

}
```

There are four built-in message types supported:

```
<?php

$this->flash->error("too bad! the form had errors");
$this->flash->success("yes!, everything went very smoothly");
$this->flash->notice("this a very important information");
$this->flash->warning("best check yo self, you're not looking too good.");
```

You can add messages with your own types:

```
<?php

$this->flash->message("debug", "this is debug message, you don't say");
```

2.31.3 Printing Messages

Messages sent to the flash service are automatically formatted with html:

```
<div class="errorMessage">too bad! the form had errors</div>
<div class="successMessage">yes!, everything went very smoothly</div>
<div class="noticeMessage">this a very important information</div>
<div class="warningMessage">best check yo self, you're not looking too good.</div>
```

As you can see, CSS classes are added automatically to the DIVs. These classes allow you to define the graphical presentation of the messages in the browser. The CSS classes can be overridden, for example, if you're using Twitter bootstrap, classes can be configured as:

```
<?php

use Phalcon\Flash\Direct as FlashDirect;

//Register the flash service with custom CSS classes
$di->set('flash', function(){
    $flash = new FlashDirect(array(
        'error' => 'alert alert-danger',
        'success' => 'alert alert-success',
        'notice' => 'alert alert-info',
        'warning' => 'alert alert-warning'
    ));
});
```

```

    });
    return $flash;
});
}

```

Then the messages would be printed as follows:

```

<div class="alert alert-danger">too bad! the form had errors</div>
<div class="alert alert-success">yes!, everything went very smoothly</div>
<div class="alert alert-info">this a very important information</div>
<div class="alert alert-warning">best check yo self, you're not looking too good.</div>

```

2.31.4 Implicit Flush vs. Session

Depending on the adapter used to send the messages, it could be producing output directly, or be temporarily storing the messages in session to be shown later. When should you use each? That usually depends on the type of redirection you do after sending the messages. For example, if you make a “forward” is not necessary to store the messages in session, but if you do a HTTP redirect then, they need to be stored in session:

```

<?php

use Phalcon\Mvc\Controller;

class ContactController extends Controller
{

    public function indexAction()
    {

    }

    public function saveAction()
    {

        // store the post

        // Using direct flash
        $this->flash->success("Your information was stored correctly!");

        // Forward to the index action
        return $this->dispatcher->forward(array("action" => "index"));
    }

}

```

Or using a HTTP redirection:

```

<?php

use Phalcon\Mvc\Controller;

class ContactController extends Controller
{

    public function indexAction()
    {

    }

```

```

public function saveAction()
{
    // store the post

    // Using session flash
    $this->flashSession->success("Your information was stored correctly!");

    // Make a full HTTP redirection
    return $this->response->redirect("contact/index");
}
}

```

In this case you need to manually print the messages in the corresponding view:

```

<!-- app/views/contact/index.phtml -->

<p><?php $this->flashSession->output() ?></p>

```

The attribute ‘flashSession’ is how the flash was previously set into the dependency injection container. You need to start the `session` first to successfully use the `flashSession` messenger.

2.32 Storing data in Session

The `Phalcon\Session` provides object-oriented wrappers to access session data.

Reasons to use this component instead of raw-sessions:

- You can easily isolate session data across applications on the same domain
- Intercept where session data is set/get in your application
- Change the session adapter according to the application needs

2.32.1 Starting the Session

Some applications are session-intensive, almost any action that performs requires access to session data. There are others who access session data casually. Thanks to the service container, we can ensure that the session is accessed only when it's clearly needed:

```

<?php

use Phalcon\Session\Adapter\Files as Session;

//Start the session the first time when some component request the session service
$di->setShared('session', function() {
    $session = new Session();
    $session->start();
    return $session;
});

```

2.32.2 Storing/Retrieving data in Session

From a controller, a view or any other component that extends `Phalcon\DI\Injectable` you can access the session service and store items and retrieve them in the following way:

```
<?php

use Phalcon\Mvc\Controller;

class UserController extends Controller
{

    public function indexAction()
    {
        //Set a session variable
        $this->session->set("user-name", "Michael");
    }

    public function welcomeAction()
    {

        //Check if the variable is defined
        if ($this->session->has("user-name")) {

            //Retrieve its value
            $name = $this->session->get("user-name");
        }
    }

}
```

2.32.3 Removing/Destroying Sessions

It's also possible remove specific variables or destroy the whole session:

```
<?php

use Phalcon\Mvc\Controller;

class UserController extends Controller
{

    public function removeAction()
    {
        //Remove a session variable
        $this->session->remove("user-name");
    }

    public function logoutAction()
    {
        //Destroy the whole session
        $this->session->destroy();
    }

}
```

2.32.4 Isolating Session Data between Applications

Sometimes a user can use the same application twice, on the same server, in the same session. Surely, if we use variables in session, we want that every application have separate session data (even though the same code and same

variable names). To solve this, you can add a prefix for every session variable created in a certain application:

```
<?php

use Phalcon\Session\Adapter\Files as Session;

//Isolating the session data
$di->set('session', function() {

    //All variables created will prefixed with "my-app-1"
    $session = new Session(
        array(
            'uniqueId' => 'my-app-1'
        )
    );

    $session->start();

    return $session;
});
```

2.32.5 Session Bags

`Phalcon\Session\Bag` is a component that helps separating session data into “namespaces”. Working by this way you can easily create groups of session variables into the application. By only setting the variables in the “bag”, it’s automatically stored in session:

```
<?php

use Phalcon\Session\Bag as SessionBag;

$user      = new SessionBag('user');
$user->setDI($di);
$user->name = "Kimbra Johnson";
$user->age  = 22;
```

2.32.6 Persistent Data in Components

Controller, components and classes that extends `Phalcon\DI\Injectable` may inject a `Phalcon\Session\Bag`. This class isolates variables for every class. Thanks to this you can persist data between requests in every class in an independent way.

```
<?php

use Phalcon\Mvc\Controller;

class UserController extends Controller
{

    public function indexAction()
    {
        // Create a persistent variable "name"
        $this->persistent->name = "Laura";
    }

    public function welcomeAction()
```

```
{  
    if (isset($this->persistent->name))  
    {  
        echo "Welcome, ", $this->persistent->name;  
    }  
}  
}
```

In a component:

```
<?php  
  
use Phalcon\Mvc\Controller;  
  
class Security extends Component  
{  
  
    public function auth()  
    {  
        // Create a persistent variable "name"  
        $this->persistent->name = "Laura";  
    }  
  
    public function getAuthName()  
    {  
        return $this->persistent->name;  
    }  
}
```

The data added to the session (`$this->session`) are available throughout the application, while persistent (`$this->persistent`) can only be accessed in the scope of the current class.

2.32.7 Implementing your own adapters

The `Phalcon\Session\AdapterInterface` interface must be implemented in order to create your own session adapters or extend the existing ones.

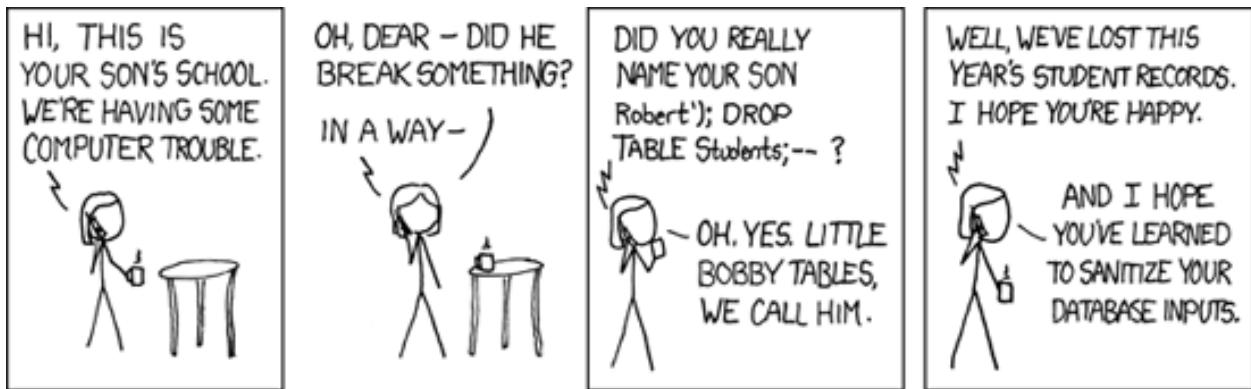

There are more adapters available for this components in the [Phalcon Incubator](#)

2.33 Filtering and Sanitizing

Sanitizing user input is a critical part of software development. Trusting or neglecting to sanitize user input could lead to unauthorized access to the content of your application, mainly user data, or even the server your application is hosted on.

[Full image \(from xkcd\)](#)

The `Phalcon\Filter` component provides a set of commonly used filters and data sanitizing helpers. It provides object-oriented wrappers around the PHP filter extension.

2.33.1 Sanitizing data

Sanitizing is the process which removes specific characters from a value, that are not required or desired by the user or application. By sanitizing input we ensure that application integrity will be intact.

```
<?php

use Phalcon\Filter;

$filter = new Filter();

// returns "someone@example.com"
$filter->sanitize("some(one)@example.com", "email");

// returns "hello"
$filter->sanitize("hello<<", "string");

// returns "100019"
$filter->sanitize("!100a019", "int");

// returns "100019.01"
$filter->sanitize("!100a019.01a", "float");
```

2.33.2 Sanitizing from Controllers

You can access a `Phalcon\Filter` object from your controllers when accessing GET or POST input data (through the `request` object). The first parameter is the name of the variable to be obtained; the second is the filter to be applied on it.

```
<?php

use Phalcon\Mvc\Controller;

class ProductsController extends Controller
{

    public function indexAction()
    {

    }

    public function saveAction()
```

```
{  
  
    // Sanitizing price from input  
    $price = $this->request->getPost("price", "double");  
  
    // Sanitizing email from input  
    $email = $this->request->getPost("customerEmail", "email");  
  
}  
  
}
```

2.33.3 Filtering Action Parameters

The next example shows you how to sanitize the action parameters within a controller action:

```
<?php  
  
use Phalcon\Mvc\Controller;  
  
class ProductsController extends Controller  
{  
  
    public function indexAction()  
    {  
  
    }  
  
    public function showAction($productId)  
    {  
        $productId = $this->filter->sanitize($productId, "int");  
    }  
  
}
```

2.33.4 Filtering data

In addition to sanitizing, Phalcon\Filter also provides filtering by removing or modifying input data to the format we expect.

```
<?php  
  
use Phalcon\Filter;  
  
$filter = new Filter();  
  
// returns "Hello"  
$filter->sanitize("<h1>Hello</h1>", "striptags");  
  
// returns "Hello"  
$filter->sanitize(" Hello ", "trim");
```

2.33.5 Types of Built-in Filters

The following are the built-in filters provided by this component:

Name	Description
string	Strip tags and escapes HTML entities, including single and double quotes.
email	Remove all characters except letters, digits and !#\$%&*+-=?^_`{ }~@.[].
int	Remove all characters except digits, plus and minus sign.
float	Remove all characters except digits, dot, plus and minus sign.
alphanum	Remove all characters except [a-zA-Z0-9]
striptags	Applies the <code>strip_tags</code> function
trim	Applies the <code>trim</code> function
lower	Applies the <code>strtolower</code> function
upper	Applies the <code>strtoupper</code> function

2.33.6 Creating your own Filters

You can add your own filters to `Phalcon\Filter`. The filter function could be an anonymous function:

```
<?php

use Phalcon\Filter;

$filter = new Filter();

// Using an anonymous function
$filter->add('md5', function($value) {
    return preg_replace('/[^0-9a-f]/', '', $value);
});

// Sanitize with the "md5" filter
$filtered = $filter->sanitize($possibleMd5, "md5");
```

Or, if you prefer, you can implement the filter in a class:

```
<?php

use Phalcon\Filter;

class IPv4Filter
{

    public function filter($value)
    {
        return filter_var($value, FILTER_VALIDATE_IP, FILTER_FLAG_IPV4);
    }
}

$filter = new Filter();

// Using an object
$filter->add('ipv4', new IPv4Filter());

// Sanitize with the "ipv4" filter
$filteredIp = $filter->sanitize("127.0.0.1", "ipv4");
```

2.33.7 Complex Sanitizing and Filtering

PHP itself provides an excellent filter extension you can use. Check out its documentation: [Data Filtering at PHP Documentation](#)

2.33.8 Implementing your own Filter

The `Phalcon\FilterInterface` interface must be implemented to create your own filtering service replacing the one provided by Phalcon.

2.34 Contextual Escaping

Websites and Web applications are vulnerable to [XSS](#) attacks, despite PHP provides escaping functionality, in some contexts those are not sufficient/appropriate. `Phalcon\Escaper` provides contextual escaping, this component is written in C providing the minimal overhead when escaping different kinds of texts.

We designed this component based on the [XSS \(Cross Site Scripting\) Prevention Cheat Sheet](#) created by the OWASP

Additionally, this component relies on `mbstring` to support almost any charset.

To illustrate how this component works and why it is important, consider the following example:

```
<?php

    //Document title with malicious extra HTML tags
    $maliciousTitle = '</title><script>alert(1)</script>';

    //Malicious CSS class name
    $className      = ';'`(';

    //Malicious CSS font name
    $fontName       = 'Verdana"</style>';

    //Malicious Javascript text
    $javascriptText = ''; </script>Hello';

    //Create an escaper
    $e              = new Phalcon\Escaper();

?>

<html>
<head>
    <meta http-equiv="Content-Type" content="text/html; charset=utf-8"/>

    <title><?php echo $e->escapeHtml($maliciousTitle) ?></title>

    <style type="text/css">
        .<?php echo $e->escapeCss($className) ?> {
            font-family : "<?php echo $e->escapeCss($fontName) ?>";
            color: red;
        }
    </style>

</head>
```

```
<body>

<div class='<?php echo $e->escapeHtmlAttr($className) ?>'>hello</div>

<script>var some = '<?php echo $e->escapeJs($javascriptText) ?>'</script>

</body>
</html>
```

Which produces the following:

```

1
2
3     <html>
4     <head>
5         <meta http-equiv="Content-Type" content="text/html; charset=utf-8"/>
6
7         <title>&lt;/title&gt;&lt;script&gt;alert(1)&lt;/script&gt;</title>
8
9         <style type="text/css">
10            .\3c \2f style\3e {
11                font-family : "Verdana\22 \3c \2f style\3e ";
12                color: red;
13            }
14        </style>
15
16    </head>
17
18    <body>
19
20        <div class='&#x3c &#x2f style&#x3e '>hello</div>
21
22        <script>var some = '\x27\x3b\x3c\x2fscript\x3eHello'</script>
23
24    </body>
25    </html>
26

```

Every text was escaped according to its context. Use the appropriate context is important to avoid XSS attacks.

2.34.1 Escaping HTML

The most common situation when inserting unsafe data is between HTML tags:

```
<div class="comments"><!-- Escape untrusted data here! --></div>
```

You can escape those data using the `escapeHtml` method:

```
<div class="comments"><?php echo $e->escapeHtml('></div><h1>myattack</h1>'); ?></div>
```

Which produces:

```
<div class="comments">&gt; &lt;/div&gt; &lt;h1&gt;myattack&lt;/h1&gt; </div>
```

2.34.2 Escaping HTML Attributes

Escape HTML attributes is different from escape a full HTML content. The escape works by changing every non-alphanumeric character to the form. This kind of escaping is intended to most simpler attributes excluding complex ones like 'href' or 'url':

```
<table width="Escape untrusted data here!"><tr><td>Hello</td></tr></table>
```

You can escape an HTML attribute by using the escapeHtmlAttr method:

```
<table width="<?php echo $e->escapeHtmlAttr('')><h1>Hello</table''); ?>"><tr><td>Hello</td></tr></table>
```

Which produces:

```
<table width="&#x22;&#x3e;&#x3c;h1&#x3e;Hello&#x3c;&#x2f;table"><tr><td>Hello</td></tr></table>
```

2.34.3 Escaping URLs

Some HTML attributes like 'href' or 'url' need to be escaped differently:

```
<a href="Escape untrusted data here!">Some link</a>
```

You can escape an HTML attribute by using the escapeUrl method:

```
<a href="<?php echo $e->escapeUrl('')><script>alert(1)</script><a href="#">Some link</a>
```

Which produces:

```
<a href="%22%3E%3Cscript%3Ealert%281%29%3C%2Fscript%3E%3Ca%20href%3D%22%23">Some link</a>
```

2.34.4 Escaping CSS

CSS identifiers/values can be escaped too:

```
<a style="color: Escape untrusted data here">Some link</a>
```

You can escape an HTML attribute by using the escapeCss method:

```
<a style="color: <?php echo $e->escapeCss('')><script>alert(1)</script><a href="#">Some link</a>
```

Which produces:

```
<a style="color: \22 \3e \3c script\3e alert\28 1\29 \3c \2f script\3e \3c a\20 href\3d \22 \23 ">Some link</a>
```

2.34.5 Escaping Javascript

Strings to be inserted into javascript code also must be properly escaped:

```
<script>document.title = 'Escape untrusted data here'</script>
```

You can escape an HTML attribute by using the escapeJs method:

```
<script>document.title = '<?php echo $e->escapejs(""); alert(100); var x='"; ?>'</script>
<script>document.title = '\x27; alert(100); var x\x3d\x27'</script>
```

2.35 Validation

Phalcon\Validation is an independent validation component that validates an arbitrary set of data. This component can be used to implement validation rules on data objects that do not belong to a model or collection.

The following example shows its basic usage:

```
<?php

use Phalcon\Validation;
use Phalcon\Validation\Validator\Email;
use Phalcon\Validation\Validator\PresenceOf;

$validation = new Validation();

$validation->add('name', new PresenceOf(array(
    'message' => 'The name is required'
)));

$validation->add('email', new PresenceOf(array(
    'message' => 'The e-mail is required'
)));

$validation->add('email', new Email(array(
    'message' => 'The e-mail is not valid'
)));

$messages = $validation->validate($_POST);
if (count($messages)) {
    foreach ($messages as $message) {
        echo $message, '  
';
    }
}
```

The loosely-coupled design of this component allows you to create your own validators along with the ones provided by the framework.

2.35.1 Initializing Validation

Validation chains can be initialized in a direct manner by just adding validators to the Phalcon\Validation object. You can put your validations in a separate file for better re-use code and organization:

```
<?php

use Phalcon\Validation;
use Phalcon\Validation\Validator\Email;
use Phalcon\Validation\Validator\PresenceOf;

class MyValidation extends Validation
{
    public function initialize()
```

```

{
    $this->add('name', new PresenceOf(array(
        'message' => 'The name is required'
    )));
    $this->add('email', new PresenceOf(array(
        'message' => 'The e-mail is required'
    )));
    $this->add('email', new Email(array(
        'message' => 'The e-mail is not valid'
    )));
}
}

```

Then initialize and use your own validator:

```

<?php

$validation = new MyValidation();

$messages = $validation->validate($_POST);
if (count($messages)) {
    foreach ($messages as $message) {
        echo $message, '<br>';
    }
}

```

2.35.2 Validators

Phalcon exposes a set of built-in validators for this component:

Name	Explanation	Example
PresenceOf	Validates that a field's value is not null or empty string.	Example
Identical	Validates that a field's value is the same as a specified value	Example
Email	Validates that field contains a valid email format	Example
ExclusionIn	Validates that a value is not within a list of possible values	Example
InclusionIn	Validates that a value is within a list of possible values	Example
Regex	Validates that the value of a field matches a regular expression	Example
StringLength	Validates the length of a string	Example
Between	Validates that a value is between two values	Example
Confirmation	Validates that a value is the same as another present in the data	Example
Url	Validates that field contains a valid URL	Example

The following example explains how to create additional validators for this component:

```

<?php

use Phalcon\Validation\Message;
use Phalcon\Validation\Validator;
use Phalcon\Validation\ValidatorInterface;

class IpValidator extends Validator implements ValidatorInterface
{
    /**
     * Executes the validation
     */
}
```

```

/*
 * @param Phalcon\Validation $validator
 * @param string $attribute
 * @return boolean
 */
public function validate($validator, $attribute)
{
    $value = $validator->getValue($attribute);

    if (!filter_var($value, FILTER_VALIDATE_IP, FILTER_FLAG_IPV4 | FILTER_FLAG_IPV6)) {

        $message = $this->getOption('message');
        if (!$message) {
            $message = 'The IP is not valid';
        }

        $validator->appendMessage(new Message($message, $attribute, 'Ip'));

        return false;
    }

    return true;
}

```

It is important that validators return a valid boolean value indicating if the validation was successful or not.

2.35.3 Validation Messages

`Phalcon\Validation` has a messaging subsystem that provides a flexible way to output or store the validation messages generated during the validation processes.

Each message consists of an instance of the class `Phalcon\Validation\Message`. The set of messages generated can be retrieved with the `getMessages()` method. Each message provides extended information like the attribute that generated the message or the message type:

```

<?php

$messages = $validation->validate();
if (count($messages)) {
    foreach ($validation->getMessages() as $message) {
        echo "Message: ", $message->getMessage(), "\n";
        echo "Field: ", $message->getField(), "\n";
        echo "Type: ", $message->getType(), "\n";
    }
}

```

The `getMessages()` method can be overridden in a validation class to replace/translate the default messages generated by the validators:

```

<?php

use Phalcon\Validation;

class MyValidation extends Validation
{

    public function initialize()

```

```
{  
    // ...  
  
    public function getMessages()  
{  
        $messages = array();  
        foreach (parent::getMessages() as $message) {  
            switch ($message->getType()) {  
                case 'PresenceOf':  
                    $messages[] = 'The field ' . $message->getField() . ' is mandatory';  
                    break;  
            }  
        }  
        return $messages;  
    }  
}
```

Or you can pass a ‘message’ parameter to change the default message in each validator:

```
<?php  
  
use Phalcon\Validation\Validator\Email;  
  
$validation->add('email', new Email(array(  
    'message' => 'The e-mail is not valid'  
)) );
```

By default, ‘getMessages’ returns all the messages generated during validation. You can filter messages for a specific field using the ‘filter’ method:

```
<?php  
  
$messages = $validation->validate();  
if (count($messages)) {  
    //Filter only the messages generated for the field 'name'  
    foreach ($validation->getMessages()->filter('name') as $message) {  
        echo $message;  
    }  
}
```

2.35.4 Filtering of Data

Data can be filtered prior to the validation ensuring that malicious or incorrect data is not validated.

```
<?php  
  
use Phalcon\Validation;  
  
$validation = new Validation();  
  
$validation  
    ->add('name', new PresenceOf(array(  
        'message' => 'The name is required'  
    )) )  
    ->add('email', new PresenceOf(array(  
        'message' => 'The email is required'
```

```

    )));

//Filter any extra space
$validation->setFilters('name', 'trim');
$validation->setFilters('email', 'trim');

```

Filtering and sanitizing is performed using the `filter:` component. You can add more filters to this component or use the built-in ones.

2.35.5 Validation Events

When validations are organized in classes, you can implement the ‘beforeValidation’ and ‘afterValidation’ methods to perform additional checks, filters, clean-up, etc. If ‘beforeValidation’ method returns false the validation is automatically cancelled:

```

<?php

use Phalcon\Validation;

class LoginValidation extends Validation
{

    public function initialize()
    {
        // ...
    }

    /**
     * Executed before validation
     *
     * @param array $data
     * @param object $entity
     * @param Phalcon\Validation\Message\Group $messages
     * @return bool
     */
    public function beforeValidation($data, $entity, $messages)
    {
        if ($this->request->getHttpHost() != 'admin.mydomain.com') {
            $messages->appendMessage(new Message('Only users can log on in the administration domain'));
            return false;
        }
        return true;
    }

    /**
     * Executed after validation
     *
     * @param array $data
     * @param object $entity
     * @param Phalcon\Validation\Message\Group $messages
     */
    public function afterValidation($data, $entity, $messages)
    {
        //.... add additional messages or perform more validations
    }
}

```

2.36 Cancelling Validations

By default all validators assigned to a field are tested regardless if one of them have failed or not. You can change this behavior by telling the validation component which validator may stop the validation:

```
<?php

use Phalcon\Validation;
use Phalcon\Validation\Validator\Regex;
use Phalcon\Validation\Validator\PresenceOf;

$validation = new Validation();

$validation
    ->add('telephone', new PresenceOf(array(
        'message' => 'The telephone is required',
        'cancelOnFail' => true
    )))
    ->add('telephone', new Regex(array(
        'message' => 'The telephone is required',
        'pattern' => '/\+44 [0-9]+/'
    )))
    ->add('telephone', new StringLength(array(
        'messageMinimum' => 'The telephone is too short',
        'min' => 2
    )));
)
```

The first validator has the option ‘cancelOnFail’ with a value of true, therefore if that validator fails the remaining validators in the chain are not executed.

If you are creating custom validators you can dynamically stop the validation chain by setting the ‘cancelOnFail’ option:

```
<?php

use Phalcon\Validation;
use Phalcon\Validation\Message;
use Phalcon\Validation\Validator;
use Phalcon\Validation\ValidatorInterface;

class MyValidator extends Validator implements ValidatorInterface
{

    /**
     * Executes the validation
     *
     * @param Phalcon\Validation $validator
     * @param string $attribute
     * @return boolean
     */
    public function validate(Validation $validator, $attribute)
    {
        // If the attribute value is name we must stop the chain
        if ($attribute == 'name') {
            $validator->setOption('cancelOnFail', true);
        }

        //...
    }
}
```

```

    }
}
```

2.37 Avoid validate empty values

You can pass the option ‘allowEmpty’ to all the built-in validators to avoid the validation to be performed if an empty value is passed:

```
<?php

use Phalcon\Validation;
use Phalcon\Validation\Validator\Regex;

$validation = new Validation();

$validation
    ->add('telephone', new Regex(array(
        'message' => 'The telephone is required',
        'pattern' => '/\+44 [0-9]+/',
        'allowEmpty' => true
    )));
}
```

2.38 Forms

Phalcon\Forms is a component that aid the developer in the creation and maintenance of forms in web applications.

The following example shows its basic usage:

```
<?php

use Phalcon\Forms\Form;
use Phalcon\Forms\Element\Text;
use Phalcon\Forms\Element>Select;

$form = new Form();

$form->add(new Text("name"));

$form->add(new Text("telephone"));

$form->add(new Select("telephoneType", array(
    'H' => 'Home',
    'C' => 'Cell'
)));
```

Forms can be rendered based on the form definition:

```
<h1>Contacts</h1>

<form method="post">

    <p>
        <label>Name</label>
        <?php echo $form->render("name") ?>
```

```
</p>

<p>
    <label>Telephone</label>
    <?php echo $form->render("telephone") ?>
</p>

<p>
    <label>Type</label>
    <?php echo $form->render("telephoneType") ?>
</p>

<p>
    <input type="submit" value="Save" />
</p>

</form>
```

Each element in the form can be rendered as required by the developer. Internally, `Phalcon\Tag` is used to produce the right HTML for each element, you can pass additional html attributes as second parameter for render:

```
<p>
    <label>Name</label>
    <?php echo $form->render("name", array('maxlength' => 30, 'placeholder' => 'Type your name')) ?>
</p>
```

HTML Attributes also can be set in the element's definition:

```
<?php

$form->add(new Text("name", array(
    'maxlength' => 30,
    'placeholder' => 'Type your name'
)) );
```

2.38.1 Initializing forms

As seen before, forms can be initialized outside the form class by adding elements to it. You can re-use code or organize your form classes implementing the form in a separated file:

```
<?php

use Phalcon\Forms\Form;
use Phalcon\Forms\Element\Text;
use Phalcon\Forms\Element>Select;

class ContactForm extends Form
{
    public function initialize()
    {
        $this->add(new Text("name"));

        $this->add(new Text("telephone"));

        $this->add(new Select("telephoneType", TelephoneTypes::find(), array(
            'using' => array('id', 'name')
        )));
    }
}
```

```

    }
}
```

Phalcon\Forms\Form extends Phalcon\DI\Injectable so you have access to the application services if needed:

```
<?php

use Phalcon\Forms\Form;
use Phalcon\Forms\Element\Text;
use Phalcon\Forms\Element\Hidden;

class ContactForm extends Form
{

    /**
     * This method returns the default value for field 'csrf'
     */
    public function getCsrf()
    {
        return $this->security->getToken();
    }

    public function initialize()
    {

        //Set the same form as entity
        $this->setEntity($this);

        //Add a text element to capture the 'email'
        $this->add(new Text("email"));

        //Add a text element to put a hidden csrf
        $this->add(new Hidden("csrf"));
    }
}
```

The associated entity added to the form in the initialization and custom user options are passed to the form constructor:

```
<?php

use Phalcon\Forms\Form;
use Phalcon\Forms\Element\Text;
use Phalcon\Forms\Element\Hidden;

class UsersForm extends Form
{
    /**
     * Forms initializer
     *
     * @param Users $user
     * @param array $options
     */
    public function initialize($user, $options)
    {

        if ($options['edit']) {
            $this->add(new Hidden('id'));
        } else {
            $this->add(new Text('id'));
    }
}
```

```

        }

        $this->add(new Text('name'));
    }
}

```

In the form's instantiation you must use:

```
<?php

$form = new UsersForm(new Users(), array('edit' => true));
```

2.38.2 Validation

Phalcon forms are integrated with the `validation` component to offer instant validation. Built-in or custom validators could be set to each element:

```
<?php

use Phalcon\Forms\Element\Text;
use Phalcon\Validation\Validator\PresenceOf;
use Phalcon\Validation\Validator\StringLength;

$name = new Text("name");

$name->addValidator(new PresenceOf(array(
    'message' => 'The name is required'
)));

$name->addValidator(new StringLength(array(
    'min' => 10,
    'messageMinimum' => 'The name is too short'
)));

$form->add($name);
```

Then you can validate the form according to the input entered by the user:

```
<?php

if (!$form->isValid($_POST)) {
    foreach ($form->getMessages() as $message) {
        echo $message, '<br>';
    }
}
```

Validators are executed in the same order as they were registered.

By default messages generated by all the elements in the form are joined so they can be traversed using a single `foreach`, you can change this behavior to get the messages separated by the field:

```
<?php

foreach ($form->getMessages(false) as $attribute => $messages) {
    echo 'Messages generated by ', $attribute, ':', "\n";
    foreach ($messages as $message) {
        echo $message, '<br>';
    }
}
```

```

    }
}
```

Or get specific messages for an element:

```
<?php

foreach ($form->getMessagesFor('name') as $message) {
    echo $message, '<br>';
}
```

2.38.3 Filtering

A form is also able to filter data before it is validated. You can set filters in each element:

2.38.4 Setting User Options

2.38.5 Forms + Entities

An entity such as a model/collection/plain instance or just a plain PHP class can be linked to the form in order to set default values in the form's elements or assign the values from the form to the entity easily:

```
<?php

$robot = Robots::findFirst();

$form = new Form($robot);

$form->add(new Text("name"));

$form->add(new Text("year"));
```

Once the form is rendered if there is no default values assigned to the elements it will use the ones provided by the entity:

```
<?php echo $form->render('name') ?>
```

You can validate the form and assign the values from the user input in the following way:

```
<?php

$form->bind($_POST, $robot);

//Check if the form is valid
if ($form->isValid()) {

    //Save the entity
    $robot->save();
}
```

Setting up a plain class as entity also is possible:

```
<?php

class Preferences
{
```

```
public $timezone = 'Europe/Amsterdam';

public $receiveEmails = 'No';
}
```

Using this class as entity, allows the form to take the default values from it:

```
<?php

$form = new Form(new Preferences());

$form->add(new Select("timezone", array(
    'America/New_York' => 'New York',
    'Europe/Amsterdam' => 'Amsterdam',
    'America/Sao_Paulo' => 'Sao Paulo',
    'Asia/Tokyo' => 'Tokyo',
))));

$form->add(new Select("receiveEmails", array(
    'Yes' => 'Yes, please!',
    'No' => 'No, thanks'
))));
```

Entities can implement getters, which have a higher precedence than public properties. These methods give you more freedom to produce values:

```
<?php

class Preferences
{

    public $timezone;

    public $receiveEmails;

    public function getTimezone()
    {
        return 'Europe/Amsterdam';
    }

    public function getReceiveEmails()
    {
        return 'No';
    }
}
```

2.38.6 Form Elements

Phalcon provides a set of built-in elements to use in your forms, all these elements are located in the Phalcon\Forms\Element namespace:

Name	Description	Example
Text	Generate INPUT[type=text] elements	Example
Password	Generate INPUT[type=password] elements	Example
Select	Generate SELECT tag (combo lists) elements based on choices	Example
Check	Generate INPUT[type=check] elements	Example
Textarea	Generate TEXTAREA elements	Example
Hidden	Generate INPUT[type=hidden] elements	Example
File	Generate INPUT[type=file] elements	Example
Date	Generate INPUT[type=date] elements	Example
Numeric	Generate INPUT[type=number] elements	Example
Submit	Generate INPUT[type=submit] elements	Example

2.38.7 Event Callbacks

Whenever forms are implemented as classes, the callbacks: beforeValidation and afterValidation can be implemented in the form's class to perform pre-validations and post-validations:

```
<?php

use Phalcon\Mvc\Form;

class ContactForm extends Form
{
    public function beforeValidation()
    {

    }
}
```

2.38.8 Rendering Forms

You can render the form with total flexibility, the following example shows how to render each element using an standard procedure:

```
<?php

<form method="post">
    <?php
        //Traverse the form
        foreach ($form as $element) {

            //Get any generated messages for the current element
            $messages = $form->getMessagesFor($element->getName());

            if (count($messages)) {
                //Print each element
                echo '<div class="messages">';
                foreach ($messages as $message) {
                    echo $message;
                }
                echo '</div>';
            }

            echo '<p>';
            echo '<label for="' . $element->getName() . '">', $element->getLabel(), '</label>';
        }
    
```

```

        echo $element;
        echo '</p>';

    }
?>
<input type="submit" value="Send"/>
</form>
```

Or reuse the logic in your form class:

```

<?php

use Phalcon\Forms\Form;

class ContactForm extends Form
{
    public function initialize()
    {
        //...
    }

    public function renderDecorated($name)
    {
        $element = $this->get($name);

        //Get any generated messages for the current element
        $messages = $this->getMessagesFor($element->getName());

        if (count($messages)) {
            //Print each element
            echo '<div class="messages">';
            foreach ($messages as $message) {
                echo $this->flash->error($message);
            }
            echo '</div>';
        }

        echo '<p>';
        echo '<label for=""', $element->getName(), '">', $element->getLabel(), '</label>';
        echo $element;
        echo '</p>';
    }
}
```

In the view:

```

<?php

echo $element->renderDecorated('name');

echo $element->renderDecorated('telephone');
```

2.38.9 Creating Form Elements

In addition to the form elements provided by Phalcon you can create your own custom elements:

```
<?php

use Phalcon\Forms\Element;

class MyElement extends Element
{
    public function render($attributes=null)
    {
        $html = //.... produce some html
        return $html;
    }
}
```

2.38.10 Forms Manager

This component provides a forms manager that can be used by the developer to register forms and access them via the service locator:

```
<?php

use Phalcon\Forms\Manager as FormsManager;

$di['forms'] = function() {
    return new FormsManager();
};
```

Forms are added to the forms manager and referenced by a unique name:

```
<?php

$this->forms->set('login', new LoginForm());
```

Using the unique name, forms can be accessed in any part of the application:

```
<?php

echo $this->forms->get('login')->render();
```

2.38.11 External Resources

- Vökuró, is a sample application that uses the forms builder to create and manage forms, [[Github](#)]

2.39 Reading Configurations

`Phalcon\Config` is a component used to read configuration files of various formats (using adapters) into PHP objects for use in an application.

2.39.1 File Adapters

The adapters available are:

File Type	Description
Ini	Uses INI files to store settings. Internally the adapter uses the PHP function parse_ini_file.
Array	Uses PHP multidimensional arrays to store settings. This adapter offers the best performance.

2.39.2 Native Arrays

The next example shows how to convert native arrays into Phalcon\Config objects. This option offers the best performance since no files are read during this request.

```
<?php

use Phalcon\Config;

$settings = array(
    "database" => array(
        "adapter"      => "Mysql",
        "host"         => "localhost",
        "username"     => "scott",
        "password"     => "cheetah",
        "dbname"       => "test_db",
    ),
    "app" => array(
        "controllersDir" => "../app/controllers/",
        "modelsDir"       => "../app/models/",
        "viewsDir"        => "../app/views/",
    ),
    "mysetting" => "the-value"
);

$config = new Config($settings);

echo $config->app->controllersDir, "\n";
echo $config->database->username, "\n";
echo $config->mysetting, "\n";
```

If you want to better organize your project you can save the array in another file and then read it.

```
<?php

use Phalcon\Config;

require "config/config.php";
$config = new Config($settings);
```

2.39.3 Reading INI Files

Ini files are a common way to store settings. Phalcon\Config uses the optimized PHP function parse_ini_file to read these files. Files sections are parsed into sub-settings for easy access.

```
[database]
adapter = Mysql
host = localhost
username = scott
password = cheetah
dbname = test_db
```

```
[phalcon]
controllersDir = "../app/controllers/"
modelsDir      = "../app/models/"
viewsDir       = "../app/views/"

[models]
metadata.adapter = "Memory"
```

You can read the file as follows:

```
<?php

use Phalcon\Config\Adapter\Ini as ConfigIni;

$config = new ConfigIni("path/config.ini");

echo $config->phalcon->controllersDir, "\n";
echo $config->database->username, "\n";
echo $config->models->metadata->adapter, "\n";
```

2.39.4 Merging Configurations

Phalcon\Config can recursively merge the properties of one configuration object into another. New properties are added and existing properties are updated.

```
<?php

use Phalcon\Config;

$config = new Config(array(
    'database' => array(
        'host'    => 'localhost',
        'dbname'  => 'test_db'
    ),
    'debug'   => 1,
));

$config2 = new Config(array(
    'database' => array(
        'dbname'  => 'production_db',
        'username' => 'scott',
        'password' => 'secret',
    ),
    'logging' => 1,
));

$config->merge($config2);

print_r($config);
```

The above code produces the following:

```
Phalcon\Config Object
(
    [database] => Phalcon\Config Object
    (
        [host] => localhost
```

```
[dbname]    => production_db
[username]  => scott
[password]  => secret
)
[debug]    => 1
[logging]   => 1
)
```

There are more adapters available for this components in the [Phalcon Incubator](#)

2.40 Pagination

The process of pagination takes place when we need to present big groups of arbitrary data gradually. Phalcon\Paginator offers a fast and convenient way to split these sets of data browsable pages.

2.40.1 Data Adapters

This component makes use of adapters to encapsulate different sources of data:

Adapter	Description
Na-tiveAr-ray	Use a PHP array as source data
Model	Use a Phalcon\Mvc\Model\Resultset object as source data. Since PDO doesn't support scrollable cursors this adapter shouldn't be used to paginate a large number of records
Query-Builder	Use a Phalcon\Mvc\Model\Query\Builder object as source data

2.40.2 Examples

In the example below, the paginator will use as its source data the result of a query from a model, and limit the displayed data to 10 records per page:

```
<?php

use Phalcon\Paginator\Adapter\Model as PaginatorModel;

// Current page to show
// In a controller this can be:
// $this->request->getQuery('page', 'int'); // GET
// $this->request->getPost('page', 'int'); // POST
$currentPage = (int) $_GET["page"];

// The data set to paginate
$robots      = Robots::find();

// Create a Model paginator, show 10 rows by page starting from $currentPage
$paginator   = new PaginatorModel(
    array(
        "data"  => $robots,
        "limit" => 10,
        "page"  => $currentPage
    )
)
```

```
) ;

// Get the paginated results
$page = $paginator->getPaginate();
```

Variable `$currentPage` controls the page to be displayed. The `$paginator->getPaginate()` returns a `$page` object that contains the paginated data. It can be used for generating the pagination:

```
<table>
    <tr>
        <th>Id</th>
        <th>Name</th>
        <th>Type</th>
    </tr>
    <?php foreach ($page->items as $item) { ?>
    <tr>
        <td><?php echo $item->id; ?></td>
        <td><?php echo $item->name; ?></td>
        <td><?php echo $item->type; ?></td>
    </tr>
    <?php } ?>
</table>
```

The `$page` object also contains navigation data:

```
<a href="/robots/search">First</a>
<a href="/robots/search?page=<?= $page->before; ?>">Previous</a>
<a href="/robots/search?page=<?= $page->next; ?>">Next</a>
<a href="/robots/search?page=<?= $page->last; ?>">Last</a>

<?php echo "You are in page ", $page->current, " of ", $page->total_pages; ?>
```

2.40.3 Adapters Usage

An example of the source data that must be used for each adapter:

```
<?php

use Phalcon\Paginator\Adapter\Model as PaginatorModel;
use Phalcon\Paginator\Adapter\NativeArray as PaginatorArray;
use Phalcon\Paginator\QueryBuilder as PaginatorQueryBuilder;

//Passing a resultset as data
$paginator = new PaginatorModel(
    array(
        "data" => Products::find(),
        "limit" => 10,
        "page" => $currentPage
    )
);

//Passing an array as data
$paginator = new PaginatorArray(
    array(
        "data" => array(
            array('id' => 1, 'name' => 'Artichoke'),
            array('id' => 2, 'name' => 'Carrots'),

```

```
        array('id' => 3, 'name' => 'Beet'),
        array('id' => 4, 'name' => 'Lettuce'),
        array('id' => 5, 'name' => '')
    ),
    "limit" => 2,
    "page"  => $currentPage
)
);

//Passing a querybuilder as data

$builder = $this->modelsManager->createBuilder()
->columns('id, name')
->from('Robots')
->orderBy('name');

$paginator = new PaginatorQueryBuilder(array(
    "builder" => $builder,
    "limit"   => 20,
    "page"    => 1
));

```

2.40.4 Page Attributes

The \$page object has the following attributes:

Attribute	Description
items	The set of records to be displayed at the current page
current	The current page
before	The previous page to the current one
next	The next page to the current one
last	The last page in the set of records
total_pages	The number of pages
total_items	The number of items in the source data

2.40.5 Implementing your own adapters

The `Phalcon\Paginator\AdapterInterface` interface must be implemented in order to create your own paginator adapters or extend the existing ones:

```
<?php

use Phalcon\Paginator\AdapterInterface as PaginatorInterface;

class MyPaginator implements PaginatorInterface
{

    /**
     * Adapter constructor
     *
     * @param array $config
     */
    public function __construct($config);

    /**

```

```

 * Set the current page number
 *
 * @param int $page
 */
public function setCurrentPage($page);

/**
 * Returns a slice of the resultset to show in the pagination
 *
 * @return stdClass
 */
public function getPaginate();

}

```

2.41 Improving Performance with Cache

Phalcon provides the `Phalcon\Cache` class allowing faster access to frequently used or already processed data. `Phalcon\Cache` is written in C, achieving higher performance and reducing the overhead when getting items from the backends. This class uses an internal structure of frontend and backend components. Front-end components act as input sources or interfaces, while backend components offer storage options to the class.

2.41.1 When to implement cache?

Although this component is very fast, implementing it in cases that are not needed could lead to a loss of performance rather than gain. We recommend you check this cases before using a cache:

- You are making complex calculations that every time return the same result (changing infrequently)
- You are using a lot of helpers and the output generated is almost always the same
- You are accessing database data constantly and these data rarely change

NOTE Even after implementing the cache, you should check the hit ratio of your cache over a period of time. This can easily be done, especially in the case of Memcache or Apc, with the relevant tools that backends provide.

2.41.2 Caching Behavior

The caching process is divided into 2 parts:

- **Frontend:** This part is responsible for checking if a key has expired and perform additional transformations to the data before storing and after retrieving them from the backend-
- **Backend:** This part is responsible for communicating, writing/reading the data required by the frontend.

2.41.3 Caching Output Fragments

An output fragment is a piece of HTML or text that is cached as is and returned as is. The output is automatically captured from the `ob_*` functions or the PHP output so that it can be saved in the cache. The following example demonstrates such usage. It receives the output generated by PHP and stores it into a file. The contents of the file are refreshed every 172800 seconds (2 days).

The implementation of this caching mechanism allows us to gain performance by not executing the helper Phalcon\Tag::linkTo call whenever this piece of code is called.

```
<?php

use Phalcon\Tag;
use Phalcon\Cache\Backend\File as BackFile;
use Phalcon\Cache\Frontend\Output as FrontOutput;

//Create an Output frontend. Cache the files for 2 days
$frontCache = new FrontOutput(array(
    "lifetime" => 172800
));

// Create the component that will cache from the "Output" to a "File" backend
// Set the cache file directory - it's important to keep the "/" at the end of
// the value for the folder
$cache = new BackFile($frontCache, array(
    "cacheDir" => "../app/cache/"
));

// Get/Set the cache file to ../app/cache/my-cache.html
$content = $cache->start("my-cache.html");

// If $content is null then the content will be generated for the cache
if ($content === null) {

    //Print date and time
    echo date("r");

    //Generate a link to the sign-up action
    echo Tag::linkTo(
        array(
            "user/signup",
            "Sign Up",
            "class" => "signup-button"
        )
    );

    // Store the output into the cache file
    $cache->save();
}

} else {

    // Echo the cached output
    echo $content;
}
```

NOTE In the example above, our code remains the same, echoing output to the user as it has been doing before. Our cache component transparently captures that output and stores it in the cache file (when the cache is generated) or it sends it back to the user pre-compiled from a previous call, thus avoiding expensive operations.

2.41.4 Caching Arbitrary Data

Caching just data is equally important for your application. Caching can reduce database load by reusing commonly used (but not updated) data, thus speeding up your application.

File Backend Example

One of the caching adapters is ‘File’. The only key area for this adapter is the location of where the cache files will be stored. This is controlled by the `cacheDir` option which *must* have a backslash at the end of it.

```
<?php

use Phalcon\Cache\Backend\File as BackFile;
use Phalcon\Cache\Frontend\Data as FrontData;

// Cache the files for 2 days using a Data frontend
$frontCache = new FrontData(array(
    "lifetime" => 172800
));

// Create the component that will cache "Data" to a "File" backend
// Set the cache file directory - important to keep the "/" at the end of
// of the value for the folder
$cache = new BackFile($frontCache, array(
    "cacheDir" => "../app/cache/"
));

// Try to get cached records
$cacheKey = 'robots_order_id.cache';
$robots = $cache->get($cacheKey);
if ($robots === null) {

    // $robots is null because of cache expiration or data does not exist
    // Make the database call and populate the variable
    $robots = Robots::find(array("order" => "id"));

    // Store it in the cache
    $cache->save($cacheKey, $robots);
}

// Use $robots :)
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}
```

Memcached Backend Example

The above example changes slightly (especially in terms of configuration) when we are using a Memcached backend.

```
<?php

use Phalcon\Cache\Frontend\Data as FrontData;
use Phalcon\Cache\Backend\Libmemcached as BackMemCached;

//Cache data for one hour
$frontCache = new FrontData(array(
    "lifetime" => 3600
));

// Create the component that will cache "Data" to a "Memcached" backend
// Memcached connection settings
$cache = new BackMemCached($frontCache, array(
```

```
"servers" => array(
    array(
        "host"      => "127.0.0.1",
        "port"      => "11211",
        "weight"    => "1"
    )
)
));
// Try to get cached records
$cacheKey = 'robots_order_id.cache';
$robots   = $cache->get($cacheKey);
if ($robots === null) {

    // $robots is null because of cache expiration or data does not exist
    // Make the database call and populate the variable
    $robots = Robots::find(array("order" => "id"));

    // Store it in the cache
    $cache->save($cacheKey, $robots);
}

// Use $robots :)
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}
```

2.41.5 Querying the cache

The elements added to the cache are uniquely identified by a key. In the case of the File backend, the key is the actual filename. To retrieve data from the cache, we just have to call it using the unique key. If the key does not exist, the get method will return null.

```
<?php

// Retrieve products by key "myProducts"
$products = $cache->get("myProducts");
```

If you want to know which keys are stored in the cache you could call the queryKeys method:

```
<?php

// Query all keys used in the cache
$keys = $cache->queryKeys();
foreach ($keys as $key) {
    $data = $cache->get($key);
    echo "Key=", $key, " Data=", $data;
}

//Query keys in the cache that begins with "my-prefix"
$keys = $cache->queryKeys("my-prefix");
```

2.41.6 Deleting data from the cache

There are times where you will need to forcibly invalidate a cache entry (due to an update in the cached data). The only requirement is to know the key that the data have been stored with.

```
<?php

// Delete an item with a specific key
$cache->delete("someKey");

// Delete all items from the cache
$keys = $cache->queryKeys();
foreach ($keys as $key) {
    $cache->delete($key);
}
```

2.41.7 Checking cache existence

It is possible to check if a cache already exists with a given key:

```
<?php

if ($cache->exists("someKey")) {
    echo $cache->get("someKey");
} else {
    echo "Cache does not exists!";
}
```

2.41.8 Lifetime

A “lifetime” is a time in seconds that a cache could live without expire. By default, all the created caches use the lifetime set in the frontend creation. You can set a specific lifetime in the creation or retrieving of the data from the cache:

Setting the lifetime when retrieving:

```
<?php

$cacheKey = 'my.cache';

//Setting the cache when getting a result
$robots = $cache->get($cacheKey, 3600);
if ($robots === null) {

    $robots = "some robots";

    // Store it in the cache
    $cache->save($cacheKey, $robots);
}
```

Setting the lifetime when saving:

```
<?php

$cacheKey = 'my.cache';

$robots = $cache->get($cacheKey);
if ($robots === null) {

    $robots = "some robots";
```

```
//Setting the cache when saving data
$cache->save($cacheKey, $robots, 3600);
}
```

2.41.9 Multi-Level Cache

This feature of the cache component, allows the developer to implement a multi-level cache. This new feature is very useful because you can save the same data in several cache locations with different lifetimes, reading first from the one with the faster adapter and ending with the slowest one until the data expires:

```
<?php

use Phalcon\Cache\Multiple;
use Phalcon\Cache\Backend\Apc as ApcCache;
use Phalcon\Cache\Backend\File as FileCache;
use Phalcon\Cache\Frontend\Data as DataFrontend;
use Phalcon\Cache\Backend\Memcache as MemcacheCache;

$ultraFastFrontend = new DataFrontend(array(
    "lifetime" => 3600
));

$fastFrontend = new DataFrontend(array(
    "lifetime" => 86400
));

$slowFrontend = new DataFrontend(array(
    "lifetime" => 604800
));

//Backends are registered from the fastest to the slower
$cache = new Multiple(array(
    new ApcCache($ultraFastFrontend, array(
        "prefix" => 'cache',
    )),
    new MemcacheCache($fastFrontend, array(
        "prefix" => 'cache',
        "host"   => "localhost",
        "port"   => "11211"
    )),
    new FileCache($slowFrontend, array(
        "prefix"   => 'cache',
        "cacheDir" => "../app/cache/"
    ))
));
$cache->save('my-key', $data);
```

2.41.10 Frontend Adapters

The available frontend adapters that are used as interfaces or input sources to the cache are:

Adapter	Description	Example
Output	Read input data from standard PHP output	Phalcon\Cache\Frontend\Output
Data	It's used to cache any kind of PHP data (big arrays, objects, text, etc). Data is serialized before stored in the backend.	Phalcon\Cache\Frontend\Data
Base64	It's used to cache binary data. The data is serialized using base64_encode before be stored in the backend.	Phalcon\Cache\Frontend\Base64
Json	Data is encoded in JSON before be stored in the backend. Decoded after be retrieved. This frontend is useful to share data with other languages or frameworks.	Phalcon\Cache\Frontend\Json
Ig-Binary	It's used to cache any kind of PHP data (big arrays, objects, text, etc). Data is serialized using IgBinary before be stored in the backend.	Phalcon\Cache\Frontend\Igbinary
None	It's used to cache any kind of PHP data without serializing them.	Phalcon\Cache\Frontend\None

Implementing your own Frontend adapters

The Phalcon\Cache\FrontendInterface interface must be implemented in order to create your own frontend adapters or extend the existing ones.

2.41.11 Backend Adapters

The backend adapters available to store cache data are:

Adapter	Description	Info	Required Extensions	Example
File	Stores data to local plain files			Phalcon\Cache\Backend\File
Memcached	Stores data to a memcached server	Memcached	memcache	Phalcon\Cache\Backend\Memcached
APC	Stores data to the Alternative PHP Cache (APC)	APC	APC extension	Phalcon\Cache\Backend\Apc
Mongo	Stores data to Mongo Database	MongoDb	Mongo	Phalcon\Cache\Backend\Mongo
XCache	Stores data in XCache	XCache	xcache extension	Phalcon\Cache\Backend\Xcache

Implementing your own Backend adapters

The Phalcon\Cache\BackendInterface interface must be implemented in order to create your own backend adapters or extend the existing ones.

File Backend Options

This backend will store cached content into files in the local server. The available options for this backend are:

Option	Description
prefix	A prefix that is automatically prepended to the cache keys
cacheDir	A writable directory on which cached files will be placed

Memcached Backend Options

This backend will store cached content on a memcached server. The available options for this backend are:

Option	Description
prefix	A prefix that is automatically prepended to the cache keys
host	memcached host
port	memcached port
persistent	create a persistent connection to memcached?

APC Backend Options

This backend will store cached content on Alternative PHP Cache (APC). The available options for this backend are:

Option	Description
prefix	A prefix that is automatically prepended to the cache keys

Mongo Backend Options

This backend will store cached content on a MongoDB server. The available options for this backend are:

Option	Description
prefix	A prefix that is automatically prepended to the cache keys
server	A MongoDB connection string
db	Mongo database name
collection	Mongo collection in the database

XCache Backend Options

This backend will store cached content on XCache (XCache). The available options for this backend are:

Option	Description
prefix	A prefix that is automatically prepended to the cache keys

There are more adapters available for this components in the [Phalcon Incubator](#)

2.42 Security

This component aids the developer in common security tasks such as password hashing and Cross-Site Request Forgery protection (CSRF).

2.42.1 Password Hashing

Storing passwords in plain text is a bad security practice. Anyone with access to the database will immediately have access to all user accounts thus being able to engage in unauthorized activities. To combat that, many applications use the familiar one way hashing methods “[md5](#)” and “[sha1](#)”. However, hardware evolves each day, and becomes faster, these algorithms are becoming vulnerable to brute force attacks. These attacks are also known as [rainbow tables](#).

To solve this problem we can use hash algorithms as [bcrypt](#). Why bcrypt? Thanks to its “[Eksblowfish](#)” key setup algorithm we can make the password encryption as “slow” as we want. Slow algorithms make the process to calculate the real password behind a hash extremely difficult if not impossible. This will protect your for a long time from a possible attack using rainbow tables.

This component gives you the ability to use this algorithm in a simple way:

```
<?php

use Phalcon\Mvc\Controller;

class UsersController extends Controller
{

    public function registerAction()
    {

        $user = new Users();

        $login = $this->request->getPost('login');
        $password = $this->request->getPost('password');

        $user->login = $login;

        //Store the password hashed
        $user->password = $this->security->hash($password);

        $user->save();
    }

}
```

We saved the password hashed with a default work factor. A higher work factor will make the password less vulnerable as its encryption will be slow. We can check if the password is correct as follows:

```
<?php

use Phalcon\Mvc\Controller;

class SessionController extends Controller
{

    public function loginAction()
    {

        $login = $this->request->getPost('login');
        $password = $this->request->getPost('password');

        $user = Users::findFirstByLogin($login);
        if ($user) {
            if ($this->security->checkHash($password, $user->password)) {
                //The password is valid
            }
        }

        //The validation has failed
    }

}
```

The salt is generated using pseudo-random bytes with the PHP's function `openssl_random_pseudo_bytes` so is required to have the `openssl` extension loaded.

2.42.2 Cross-Site Request Forgery (CSRF) protection

This is another common attack against web sites and applications. Forms designed to perform tasks such as user registration or adding comments are vulnerable to this attack.

The idea is to prevent the form values from being sent outside our application. To fix this, we generate a [random nonce](#) (token) in each form, add the token in the session and then validate the token once the form posts data back to our application by comparing the stored token in the session to the one submitted by the form:

```
<?php echo Tag::form('session/login') ?>

    <!-- login and password inputs ... -->

    <input type="hidden" name="<?php echo $this->security->getTokenKey() ?>" value="<?php echo $this->security->getToken() ?>"/>

</form>
```

Then in the controller's action you can check if the CSRF token is valid:

```
<?php

use Phalcon\Mvc\Controller;

class SessionController extends Controller
{

    public function loginAction()
    {
        if ($this->request->isPost()) {
            if ($this->security->checkToken()) {
                //The token is ok
            }
        }
    }
}
```

Remember to add a session adapter to your Dependency Injector, otherwise the token check won't work:

```
$di->setShared('session', function() {
    $session = new Phalcon\Session\Adapter\Files();
    $session->start();
    return $session;
});
```

Adding a [captcha](#) to the form is also recommended to completely avoid the risks of this attack.

2.42.3 Setting up the component

This component is automatically registered in the services container as 'security', you can re-register it to setup its options:

```
<?php

use Phalcon\Security;

$di->set('security', function() {
```

```

$security = new Security();

//Set the password hashing factor to 12 rounds
$security->setWorkFactor(12);

return $security;
}, true);

```

2.42.4 External Resources

- Vökuró, is a sample application that uses the Security component for avoid CSRF and password hashing, [\[Github\]](#)

2.43 Encryption/Decryption

Phalcon provides encryption facilities via the `Phalcon\Crypt` component. This class offers simple object-oriented wrappers to the `mcrypt` php's encryption library.

By default, this component provides secure encryption using AES-256 (rijndael-256-cbc).

2.43.1 Basic Usage

This component is designed to provide a very simple usage:

```

<?php

use Phalcon\Crypt;

//Create an instance
$crypt      = new Crypt();

$key        = 'le password';
$text       = 'This is a secret text';

$encrypted = $crypt->encrypt($text, $key);

echo $crypt->decrypt($encrypted, $key);

```

You can use the same instance to encrypt/decrypt several times:

```

<?php

use Phalcon\Crypt;

//Create an instance
$crypt = new Crypt();

$texts = array(
    'my-key'    => 'This is a secret text',
    'other-key' => 'This is a very secret'
);

foreach ($texts as $key => $text) {

```

```
// Perform the encryption
$encrypted = $crypt->encrypt($text, $key);

// Now decrypt
echo $crypt->decrypt($encrypted, $key);
}
```

2.43.2 Encryption Options

The following options are available to change the encryption behavior:

Name	Description
Cipher	The cipher is one of the encryption algorithms supported by libmcrypt. You can see a list here
Mode	One of the encryption modes supported by libmcrypt (ecb, cbc, cfb, ofb)

Example:

```
<?php

use Phalcon\Crypt;

// Create an instance
$crypt = new Crypt();

// Use blowfish
$crypt->setCipher('blowfish');

$key    = 'le password';
$text   = 'This is a secret text';

echo $crypt->encrypt($text, $key);
```

2.43.3 Base64 Support

In order that encryption is properly transmitted (emails) or displayed (browsers) base64 encoding is usually applied to encrypted texts:

```
<?php

use Phalcon\Crypt;

// Create an instance
$crypt = new Crypt();

$key    = 'le password';
$text   = 'This is a secret text';

$encrypt = $crypt->encryptBase64($text, $key);

echo $crypt->decryptBase64($text, $key);
```

2.43.4 Setting up an Encryption service

You can set up the encryption component in the services container in order to use it from any part of the application:

```
<?php

use Phalcon\Crypt;

$di->set('crypt', function() {

    $crypt = new Crypt();

    // Set a global encryption key
    $crypt->setKey('%31.1e$i86e$f!8jz');

    return $crypt;
}, true);
```

Then, for example, in a controller you can use it as follows:

```
<?php

use Phalcon\Mvc\Controller;

class SecretsController extends Controller
{

    public function saveAction()
    {
        $secret = new Secrets();

        $text = $this->request->getPost('text');

        $secret->content = $this->crypt->encrypt($text);

        if ($secret->save()) {
            $this->flash->success('Secret was successfully created!');
        }
    }
}
```

2.44 Access Control Lists ACL

Phalcon\Acl provides an easy and lightweight management of ACLs as well as the permissions attached to them. Access Control Lists (ACL) allow an application to control access to its areas and the underlying objects from requests. You are encouraged to read more about the ACL methodology so as to be familiar with its concepts.

In summary, ACLs have roles and resources. Resources are objects which abide by the permissions defined to them by the ACLs. Roles are objects that request access to resources and can be allowed or denied access by the ACL mechanism.

2.44.1 Creating an ACL

This component is designed to initially work in memory. This provides ease of use and speed in accessing every aspect of the list. The `Phalcon\Acl` constructor takes as its first parameter an adapter used to retriever the information related to the control list. An example using the memory adapter is below:

```
<?php
```

```
use Phalcon\Acl\Adapter\Memory as AcList;

$acl = new AcList();
```

By default `Phalcon\Acl` allows access to action on resources that have not been yet defined. To increase the security level of the access list we can define a “deny” level as a default access level.

```
<?php

// Default action is deny access
$acl->setDefaultAction(Phalcon\Acl::DENY);
```

2.44.2 Adding Roles to the ACL

A role is an object that can or cannot access certain resources in the access list. As an example, we will define roles as groups of people in an organization. The `Phalcon\Acl\Role` class is available to create roles in a more structured way. Let’s add some roles to our recently created list:

```
<?php

use Phalcon\Acl\Role;

// Create some roles
$roleAdmins = new Role("Administrators", "Super-User role");
$roleGuests = new Role("Guests");

// Add "Guests" role to acl
$acl->addRole($roleGuests);

// Add "Designers" role to acl without a Phalcon\Acl\Role
$acl->addRole("Designers");
```

As you can see, roles are defined directly without using an instance.

2.44.3 Adding Resources

Resources are objects where access is controlled. Normally in MVC applications resources refer to controllers. Although this is not mandatory, the `Phalcon\Acl\Resource` class can be used in defining resources. It’s important to add related actions or operations to a resource so that the ACL can understand what it should to control.

```
<?php

use Phalcon\Acl\Resource;

// Define the "Customers" resource
$customersResource = new Resource("Customers");

// Add "customers" resource with a couple of operations
$acl->addResource($customersResource, "search");
$acl->addResource($customersResource, array("create", "update"));
```

2.44.4 Defining Access Controls

Now we’ve roles and resources. It’s time to define the ACL i.e. which roles can access which resources. This part is very important especially taking in consideration your default access level “allow” or “deny”.

```
<?php

// Set access level for roles into resources
$acl->allow("Guests", "Customers", "search");
$acl->allow("Guests", "Customers", "create");
$acl->deny("Guests", "Customers", "update");
```

The allow method designates that a particular role has granted access to a particular resource. The deny method does the opposite.

2.44.5 Querying an ACL

Once the list has been completely defined. We can query it to check if a role has a given permission or not.

```
<?php

// Check whether role has access to the operations
$acl->isAllowed("Guests", "Customers", "edit"); //Returns 0
$acl->isAllowed("Guests", "Customers", "search"); //Returns 1
$acl->isAllowed("Guests", "Customers", "create"); //Returns 1
```

2.44.6 Roles Inheritance

You can build complex role structures using the inheritance that `Phalcon\Acl\Role` provides. Roles can inherit from other roles, thus allowing access to supersets or subsets of resources. To use role inheritance, you need to pass the inherited role as the second parameter of the function call, when adding that role in the list.

```
<?php

use Phalcon\Acl\Role;

// ...

// Create some roles
$roleAdmins = new Role("Administrators", "Super-User role");
$roleGuests = new Role("Guests");

// Add "Guests" role to acl
$acl->addRole($roleGuests);

// Add "Administrators" role inheriting from "Guests" its accesses
$acl->addRole($roleAdmins, $roleGuests);
```

2.44.7 Serializing ACL lists

To improve performance `Phalcon\Acl` instances can be serialized and stored in APC, session, text files or a database table so that they can be loaded at will without having to redefine the whole list. You can do that as follows:

```
<?php

use Phalcon\Acl\Adapter\Memory as AclList;

// ...
```

```
// Check whether acl data already exist
if (!is_file("app/security/acl.data")) {

    $acl = new AclList();

    //... Define roles, resources, access, etc

    // Store serialized list into plain file
    file_put_contents("app/security/acl.data", serialize($acl));
} else {

    // Restore acl object from serialized file
    $acl = unserialize(file_get_contents("app/security/acl.data"));
}

// Use acl list as needed
if ($acl->isAllowed("Guests", "Customers", "edit")) {
    echo "Access granted!";
} else {
    echo "Access denied :(";
}
```

2.44.8 Acl Events

Phalcon\Acl is able to send events to a [EventsManager](#) if it's present. Events are triggered using the type "acl". Some events when returning boolean false could stop the active operation. The following events are supported:

Event Name	Triggered	Can stop operation?
beforeCheckAccess	Triggered before checking if a role/resource has access	Yes
afterCheckAccess	Triggered after checking if a role/resource has access	No

The following example demonstrates how to attach listeners to this component:

```
<?php

use Phalcon\Acl\Adapter\Memory as AclList;
use Phalcon\Events\Manager as EventsManager;

// ...

// Create an event manager
$eventsManager = new EventsManager();

// Attach a listener for type "acl"
$eventsManager->attach("acl", function($event, $acl) {
    if ($event->getType() == "beforeCheckAccess") {
        echo $acl->getActiveRole(),
            $acl->getActiveResource(),
            $acl->getActiveAccess();
    }
});

$acl = new AclList();

//Setup the $acl
//...
```

```
//Bind the eventsManager to the acl component
$acl->setEventsManager($eventManagers);
```

2.44.9 Implementing your own adapters

The `Phalcon\Acl\AdapterInterface` interface must be implemented in order to create your own ACL adapters or extend the existing ones.

2.45 Multi-lingual Support

The component `Phalcon\Translate` aids in creating multilingual applications. Applications using this component, display content in different languages, based on the user's chosen language supported by the application.

2.45.1 Adapters

This component makes use of adapters to read translation messages from different sources in a unified way.

Adapter	Description
NativeArray	Uses PHP arrays to store the messages. This is the best option in terms of performance.

2.45.2 Component Usage

Translation strings are stored in files. The structure of these files could vary depending of the adapter used. Phalcon gives you the freedom to organize your translation strings. A simple structure could be:

```
app/messages/en.php
app/messages/es.php
app/messages/fr.php
app/messages/zh.php
```

Each file contains an array of the translations in a key/value manner. For each translation file, keys are unique. The same array is used in different files, where keys remain the same and values contain the translated strings depending on each language.

```
<?php

//app/messages/es.php
$messages = array(
    "hi"      => "Hello",
    "bye"     => "Good Bye",
    "hi-name" => "Hello %name%",
    "song"    => "This song is %song%"
);
```

```
<?php

//app/messages/fr.php
$messages = array(
    "hi"      => "Bonjour",
    "bye"     => "Au revoir",
    "hi-name" => "Bonjour %name%",
```

```

    "song"      => "La chanson est %song%"
);

```

Implementing the translation mechanism in your application is trivial but depends on how you wish to implement it. You can use an automatic detection of the language from the user's browser or you can provide a settings page where the user can select their language.

A simple way of detecting the user's language is to parse the `$_SERVER['HTTP_ACCEPT_LANGUAGE']` contents, or if you wish, access it directly by calling `$this->request->getBestLanguage()` from an action/controller:

```

<?php

class UserController extends \Phalcon\Mvc\Controller
{

    protected function _getTranslation()
    {

        //Ask browser what is the best language
        $language = $this->request->getBestLanguage();

        //Check if we have a translation file for that lang
        if (file_exists("app/messages/".$language.".php")) {
            require "app/messages/".$language.".php";
        } else {
            // fallback to some default
            require "app/messages/en.php";
        }

        //Return a translation object
        return new \Phalcon\Translate\Adapter\NativeArray(array(
            "content" => $messages
        ));
    }

    public function indexAction()
    {
        $this->view->setVar("name", "Mike");
        $this->view->setVar("t", $this->_getTranslation());
    }
}

```

The `_getTranslation` method is available for all actions that require translations. The `$t` variable is passed to the views, and with it, we can translate strings in that layer:

```

<!-- welcome -->
<!-- String: hi => 'Hello' -->
<p><?php echo $t->_("hi"), " ", $name; ?></p>

```

The “`_`” function is returning the translated string based on the index passed. Some strings need to incorporate placeholders for calculated data i.e. Hello `%name%`. These placeholders can be replaced with passed parameters in the “`_`” function. The passed parameters are in the form of a key/value array, where the key matches the placeholder name and the value is the actual data to be replaced:

```

<!-- welcome -->
<!-- String: hi-name => 'Hello %name%' -->
<p><?php echo $t->_("hi-name", array("name" => $name)); ?></p>

```

Some applications implement multilingual on the URL such as <http://www.mozilla.org/es-ES/firefox/>. Phalcon can implement this by using a Router.

2.45.3 Implementing your own adapters

The `Phalcon\Translate\AdapterInterface` interface must be implemented in order to create your own translate adapters or extend the existing ones:

```
<?php

class MyTranslateAdapter implements Phalcon\Translate\AdapterInterface
{

    /**
     * Adapter constructor
     *
     * @param array $data
     */
    public function __construct($options);

    /**
     * Returns the translation string of the given key
     *
     * @param string $translateKey
     * @param array $placeholders
     * @return string
     */
    public function _($translateKey, $placeholders=null);

    /**
     * Returns the translation related to the given key
     *
     * @param string $index
     * @param array $placeholders
     * @return string
     */
    public function query($index, $placeholders=null);

    /**
     * Check whether is defined a translation key in the internal array
     *
     * @param string $index
     * @return bool
     */
    public function exists($index);
}
```

There are more adapters available for this components in the [Phalcon Incubator](#)

2.46 Universal Class Loader

`Phalcon\Loader` is a component that allows you to load project classes automatically, based on some predefined rules. Since this component is written in C, it provides the lowest overhead in reading and interpreting external PHP files.

The behavior of this component is based on the PHP's capability of autoloading classes. If a class that does not exist is used in any part of the code, a special handler will try to load it. `Phalcon\Loader` serves as the special handler for this operation. By loading classes on a need to load basis, the overall performance is increased since the only file reads that occur are for the files needed. This technique is called [lazy initialization](#).

With this component you can load files from other projects or vendors, this autoloader is [PSR-0](#) and [PSR-4](#) compliant. `Phalcon\Loader` offers four options to autoload classes. You can use them one at a time or combine them.

2.46.1 Registering Namespaces

If you're organizing your code using namespaces, or external libraries do so, the `registerNamespaces()` provides the autoloading mechanism. It takes an associative array, which keys are namespace prefixes and their values are directories where the classes are located in. The namespace separator will be replaced by the directory separator when the loader try to find the classes. Remember always to add a trailing slash at the end of the paths.

```
<?php

use Phalcon\Loader;

// Creates the autoloader
$loader = new Loader();

//Register some namespaces
$loader->registerNamespaces(
    array(
        "Example\Base"      => "vendor/example/base/",
        "Example\Adapter"   => "vendor/example/adapter/",
        "Example"           => "vendor/example/",
    )
);

// register autoloader
$loader->register();

// The required class will automatically include the
// file vendor/example/adapter/Some.php
$some = new Example\Adapter\Some();
```

2.46.2 Registering Prefixes

This strategy is similar to the namespaces strategy. It takes an associative array, which keys are prefixes and their values are directories where the classes are located in. The namespace separator and the “_” underscore character will be replaced by the directory separator when the loader try to find the classes. Remember always to add a trailing slash at the end of the paths.

```
<?php

use Phalcon\Loader;

// Creates the autoloader
$loader = new Loader();

//Register some prefixes
$loader->registerPrefixes(
    array(
```

```

    "Example_Base"      => "vendor/example/base/",
    "Example_Adapter"   => "vendor/example/adapter/",
    "Example_"          => "vendor/example/",
)
);

// register autoloader
$loader->register();

// The required class will automatically include the
// file vendor/example/adapter/Some.php
$some = new Example_Adapter_Some();

```

2.46.3 Registering Directories

The third option is to register directories, in which classes could be found. This option is not recommended in terms of performance, since Phalcon will need to perform a significant number of file stats on each folder, looking for the file with the same name as the class. It's important to register the directories in relevance order. Remember always add a trailing slash at the end of the paths.

```

<?php

use Phalcon\Loader;

// Creates the autoloader
$loader = new Loader();

// Register some directories
$loader->registerDirs(
    array(
        "library/MyComponent/",
        "library/OtherComponent/Other/",
        "vendor/example/adapters/",
        "vendor/example/"
    )
);

// register autoloader
$loader->register();

// The required class will automatically include the file from
// the first directory where it has been located
// i.e. library/OtherComponent/Other/Some.php
$some = new Some();

```

2.46.4 Registering Classes

The last option is to register the class name and its path. This autoloader can be very useful when the folder convention of the project does not allow for easy retrieval of the file using the path and the class name. This is the fastest method of autoloading. However the more your application grows, the more classes/files need to be added to this autoloader, which will effectively make maintenance of the class list very cumbersome and it is not recommended.

```

<?php

use Phalcon\Loader;

```

```
// Creates the autoloader
$loader = new Loader();

// Register some classes
$loader->registerClasses(
    array(
        "Some"      => "library/OtherComponent/Other/Some.php",
        "Example\Base" => "vendor/example/adapters/Example/BaseClass.php",
    )
);

// register autoloader
$loader->register();

// Requiring a class will automatically include the file it references
// in the associative array
// i.e. library/OtherComponent/Other/Some.php
$some = new Some();
```

2.46.5 Additional file extensions

Some autoloading strategies such as “prefixes”, “namespaces” or “directories” automatically append the “php” extension at the end of the checked file. If you are using additional extensions you could set it with the method “setExtensions”. Files are checked in the order as it were defined:

```
<?php

// Creates the autoloader
$loader = new \Phalcon\Loader();

//Set file extensions to check
$loader->setExtensions(array("php", "inc", "phb"));
```

2.46.6 Modifying current strategies

Additional auto-loading data can be added to existing values in the following way:

```
<?php

// Adding more directories
$loader->registerDirs(
    array(
        '../app/library/',
        '../app/plugins/'
    ),
    true
);
```

Passing “true” as second parameter will merge the current values with new ones in any strategy.

2.46.7 Security Layer

Phalcon\Loader offers a security layer sanitizing by default class names avoiding possible inclusion of unauthorized files. Consider the following example:

```
<?php

// Basic autoloader
spl_autoload_register(function($className) {
    if (file_exists($className . '.php')) {
        require $className . '.php';
    }
});
```

The above auto-loader lacks of any security check, if by mistake in a function that launch the auto-loader, a malicious prepared string is used as parameter this would allow to execute any file accessible by the application:

```
<?php

// This variable is not filtered and comes from an insecure source
$className = '../processes/important-process';

// Check if the class exists triggering the auto-loader
if (class_exists($className)) {
    //...
}
```

If ‘..../processes/important-process.php’ is a valid file, an external user could execute the file without authorization.

To avoid these or most sophisticated attacks, Phalcon\Loader removes any invalid character from the class name reducing the possibility of being attacked.

2.46.8 Autoloading Events

In the following example, the EventsManager is working with the class loader, allowing us to obtain debugging information regarding the flow of operation:

```
<?php

$eventsManager = new \Phalcon\Events\Manager();

$loader = new \Phalcon\Loader();

$loader->registerNamespaces(array(
    'Example\\Base' => 'vendor/example/base/',
    'Example\\Adapter' => 'vendor/example/adapter/',
    'Example' => 'vendor/example/'
));

// Listen all the loader events
$eventsManager->attach('loader', function($event, $loader) {
    if ($event->getType() == 'beforeCheckPath') {
        echo $loader->getCheckedPath();
    }
});

$loader->setEventsManager($eventsManager);

$loader->register();
```

Some events when returning boolean false could stop the active operation. The following events are supported:

Event Name	Triggered
beforeCheckClass	Triggered before starting the autoloading process
pathFound	Triggered when the loader locate a class
afterCheckClass	Triggered after finish the autoloading process. If this event is launched the autoloader didn't find the class file

2.46.9 Troubleshooting

Some things to keep in mind when using the universal autoloader:

- Auto-loading process is case-sensitive, the class will be loaded as it is written in the code
- Strategies based on namespaces/prefixes are faster than the directories strategy
- If a cache bytecode like APC is installed this will be used to retrieve the requested file (an implicit caching of the file is performed)

2.47 Logging

`Phalcon\Logger` is a component whose purpose is to provide logging services for applications. It offers logging to different backends using different adapters. It also offers transaction logging, configuration options, different formats and filters. You can use the `Phalcon\Logger` for every logging need your application has, from debugging processes to tracing application flow.

2.47.1 Adapters

This component makes use of adapters to store the logged messages. The use of adapters allows for a common interface for logging while switching backends if necessary. The adapters supported are:

Adapter	Description	API
File	Logs to a plain text file	<code>Phalcon\Logger\Adapter\File</code>
Stream	Logs to a PHP Streams	<code>Phalcon\Logger\Adapter\Stream</code>
Syslog	Logs to the system logger	<code>Phalcon\Logger\Adapter\Syslog</code>
Firephp	Logs to the FirePHP	<code>Phalcon\Logger\Adapter\FirePHP</code>

2.47.2 Creating a Log

The example below shows how to create a log and add messages to it:

```
<?php

use Phalcon\Logger\Adapter\File as FileAdapter;

$logger = new FileAdapter("app/logs/test.log");
$logger->log("This is a message");
$logger->log("This is an error", \Phalcon\Logger::ERROR);
$logger->error("This is another error");
```

The log generated is below:

```
[Tue, 17 Apr 15 22:09:02 -0500] [DEBUG] This is a message
[Tue, 17 Apr 15 22:09:02 -0500] [ERROR] This is an error
[Tue, 17 Apr 15 22:09:02 -0500] [ERROR] This is another error
```

2.47.3 Transactions

Logging data to an adapter i.e. File (file system) is always an expensive operation in terms of performance. To combat that, you can take advantage of logging transactions. Transactions store log data temporarily in memory and later on write the data to the relevant adapter (File in this case) in a single atomic operation.

```
<?php

use Phalcon\Logger\Adapter\File as FileAdapter;

// Create the logger
$logger = new FileAdapter("app/logs/test.log");

// Start a transaction
$logger->begin();

// Add messages
$logger->alert("This is an alert");
$logger->error("This is another error");

// Commit messages to file
$logger->commit();
```

2.47.4 Logging to Multiple Handlers

`Phalcon\Logger` can send messages to multiple handlers with a just single call:

```
<?php

use Phalcon\Logger,
    Phalcon\Logger\Multiple as MultipleStream,
    Phalcon\Logger\Adapter\File as FileAdapter,
    Phalcon\Logger\Adapter\Stream as StreamAdapter;

$logger = new MultipleStream();

$logger->push(new FileAdapter('test.log'));
$logger->push(new StreamAdapter('php://stdout'));

$logger->log("This is a message");
$logger->log("This is an error", Logger::ERROR);
$logger->error("This is another error");
```

The messages are sent to the handlers in the order they were registered.

2.47.5 Message Formatting

This component makes use of ‘formatters’ to format messages before sending them to the backend. The formatters available are:

Adapter	Description	API
Line	Formats the messages using a one-line string	<code>Phalcon\Logger\Formatter\Line</code>
Json	Prepares a message to be encoded with JSON	<code>Phalcon\Logger\Formatter\Json</code>
Syslog	Prepares a message to be sent to syslog	<code>Phalcon\Logger\Formatter\Syslog</code>

Line Formatter

Formats the messages using a one-line string. The default logging format is:

[%date%][%type%] %message%

You can change the default format using `setFormat()`, this allows you to change the format of the logged messages by defining your own. The log format variables allowed are:

Variable	Description
%message%	The message itself expected to be logged
%date%	Date the message was added
%type%	Uppercase string with message type

The example below shows how to change the log format:

```
<?php

use Phalcon\Logger\Formatter\Line as LineFormatter;

//Changing the logger format
$formatter = new LineFormatter("%date% - %message%");
$logger->setFormatter($formatter);
```

Implementing your own formatters

The `Phalcon\Logger\FormatterInterface` interface must be implemented in order to create your own logger formatter or extend the existing ones.

2.47.6 Adapters

The following examples show the basic use of each adapter:

Stream Logger

The stream logger writes messages to a valid registered stream in PHP. A list of streams is available [here](#):

```
<?php

use Phalcon\Logger\Adapter\Stream as StreamAdapter;

// Opens a stream using zlib compression
$logger = new StreamAdapter("compress.zlib://week.log.gz");

// Writes the logs to stderr
$logger = new StreamAdapter("php://stderr");
```

File Logger

This logger uses plain files to log any kind of data. By default all logger files are opened using append mode which opens the files for writing only; placing the file pointer at the end of the file. If the file does not exist, an attempt will be made to create it. You can change this mode by passing additional options to the constructor:

```
<?php

use Phalcon\Logger\Adapter\File as FileAdapter;

// Create the file logger in 'w' mode
$logger = new FileAdapter("app/logs/test.log", array(
    'mode' => 'w'
));

```

Syslog Logger

This logger sends messages to the system logger. The syslog behavior may vary from one operating system to another.

```
<?php

use Phalcon\Logger\Adapter\Syslog as SyslogAdapter;

// Basic Usage
$logger = new SyslogAdapter(null);

// Setting ident/mode/facility
$logger = new SyslogAdapter("ident-name", array(
    'option' => LOG_NDELAY,
    'facility' => LOG_MAIL
));

```

FirePHP Logger

This logger sends messages in HTTP response headers that are displayed by [FirePHP](#), a Firebug extension for Firefox.

```
<?php

use Phalcon\Logger;
use Phalcon\Logger\Adapter\Firephp as Firephp;

$logger = new Firephp("");
    $logger->log("This is a message");
    $logger->log("This is an error", Logger::ERROR);
    $logger->error("This is another error");

```

Implementing your own adapters

The `Phalcon\Logger\AdapterInterface` interface must be implemented in order to create your own logger adapters or extend the existing ones.

2.48 Annotations Parser

It is the first time that an annotations parser component is written in C for the PHP world. `Phalcon\Annotations` is a general purpose component that provides ease of parsing and caching annotations in PHP classes to be used in applications.

Annotations are read from docblocks in classes, methods and properties. An annotation can be placed at any position in the docblock:

```
<?php

/**
 * This is the class description
 *
 * @AmazingClass(true)
 */
class Example
{

    /**
     * This a property with a special feature
     *
     * @SpecialFeature
     */
    protected $someProperty;

    /**
     * This is a method
     *
     * @SpecialFeature
     */
    public function someMethod()
    {
        // ...
    }
}
```

In the above example we find some annotations in the comments, an annotation has the following syntax:

`@Annotation-Name[(param1, param2, ...)]`

Also, an annotation could be placed at any part of a docblock:

```
<?php

/**
 * This a property with a special feature
 *
 * @SpecialFeature
 *
 * More comments
 *
 * @AnotherSpecialFeature(true)
 */
```

The parser is highly flexible, the following docblock is valid:

```
<?php

/**
 * This a property with a special feature @SpecialFeature({
 * someParameter="the value", false
 *
 * }) More comments @AnotherSpecialFeature(true) @MoreAnnotations
 **/
```

However, to make the code more maintainable and understandable it is recommended to place annotations at the end of the docblock:

```
<?php

/**
 * This a property with a special feature
 * More comments
 *
 * @SpecialFeature({someParameter="the value", false})
 * @AnotherSpecialFeature(true)
 */
```

2.48.1 Reading Annotations

A reflector is implemented to easily get the annotations defined on a class using an object-oriented interface:

```
<?php

$reader = new \Phalcon\Annotations\Adapter\Memory();

//Reflect the annotations in the class Example
$reflector = $reader->get('Example');

//Read the annotations in the class' docblock
$annotations = $reflector->getClassAnnotations();

//Traverse the annotations
foreach ($annotations as $annotation) {

    //Print the annotation name
    echo $annotation->getName(), PHP_EOL;

    //Print the number of arguments
    echo $annotation->numberArguments(), PHP_EOL;

    //Print the arguments
    print_r($annotation->getArguments());
}
```

The annotation reading process is very fast, however, for performance reasons it is recommended to store the parsed annotations using an adapter. Adapters cache the processed annotations avoiding the need of parse the annotations again and again.

`\Phalcon\Annotations\Adapter\Memory` was used in the above example. This adapter only caches the annotations while the request is running, for this reason th adapter is more suitable for development. There are other adapters to swap out when the application is in production stage.

2.48.2 Types of Annotations

Annotations may have parameters or not. A parameter could be a simple literal (strings, number, boolean, null), an array, a hashed list or other annotation:

```
<?php

/**
 * Simple Annotation
 *
 * @SomeAnnotation
```

```
/*
 *
/***
 * Annotation with parameters
 *
 * @SomeAnnotation("hello", "world", 1, 2, 3, false, true)
 */

/***
 * Annotation with named parameters
 *
 * @SomeAnnotation(first="hello", second="world", third=1)
 * @SomeAnnotation(first: "hello", second: "world", third: 1)
 */

/***
 * Passing an array
 *
 * @SomeAnnotation([1, 2, 3, 4])
 * @SomeAnnotation({1, 2, 3, 4})
 */

/***
 * Passing a hash as parameter
 *
 * @SomeAnnotation({first=1, second=2, third=3})
 * @SomeAnnotation({'first'=1, 'second'=2, 'third'=3})
 * @SomeAnnotation({'first': 1, 'second': 2, 'third': 3})
 * @SomeAnnotation(['first': 1, 'second': 2, 'third': 3])
 */

/***
 * Nested arrays/hashes
 *
 * @SomeAnnotation({"name"="SomeName", "other"={
 *     "foo1": "bar1", "foo2": "bar2", {1, 2, 3},
 * } })
 */

/***
 * Nested Annotations
 *
 * @SomeAnnotation(first=@AnotherAnnotation(1, 2, 3))
 */
```

2.48.3 Practical Usage

Next we will explain some practical examples of annotations in PHP applications:

Cache Enabler with Annotations

Let's pretend we've the following controller and the developer wants to create a plugin that automatically start the cache if the latest action executed is marked as cacheable. First off all we register a plugin in the Dispatcher service to be notified when a route is executed:

```
<?php

$di['dispatcher'] = function() {

    $eventsManager = new \Phalcon\Events\Manager();

    //Attach the plugin to 'dispatch' events
    $eventsManager->attach('dispatch', new CacheEnablerPlugin());

    $dispatcher = new \Phalcon\Mvc\Dispatcher();
    $dispatcher->setEventsManager($eventsManager);
    return $dispatcher;
};
```

CacheEnablerPlugin is a plugin that intercept every action executed in the dispatcher enabling the cache if needed:

```
<?php

/**
 * Enables the cache for a view if the latest
 * executed action has the annotation @Cache
 */
class CacheEnablerPlugin extends \Phalcon\Mvc\User\Plugin
{

    /**
     * This event is executed before every route is executed in the dispatcher
     *
     */
    public function beforeExecuteRoute($event, $dispatcher)
    {

        //Parse the annotations in the method currently executed
        $annotations = $this->annotations->getMethod(
            $dispatcher->getActiveController(),
            $dispatcher->getActiveMethod()
        );

        //Check if the method has an annotation 'Cache'
        if ($annotations->has('Cache')) {

            //The method has the annotation 'Cache'
            $annotation = $annotations->get('Cache');

            //Get the lifetime
            $lifetime = $annotation->getNamedParameter('lifetime');

            $options = array('lifetime' => $lifetime);

            //Check if there is an user defined cache key
            if ($annotation->hasNamedParameter('key')) {
                $options['key'] = $annotation->getNamedParameter('key');
            }

            //Enable the cache for the current method
            $this->view->cache($options);
        }
    }
}
```

```
}
```

Now, we can use the annotation in a controller:

```
<?php

class NewsController extends \Phalcon\Mvc\Controller
{

    public function indexAction()
    {

    }

    /**
     * This is a comment
     *
     * @Cache(lifetime=86400)
     */
    public function showAllAction()
    {
        $this->view->article = Articles::find();
    }

    /**
     * This is a comment
     *
     * @Cache(key="my-key", lifetime=86400)
     */
    public function showAction($slug)
    {
        $this->view->article = Articles::findFirstByTitle($slug);
    }
}
```

Choose template to render

In this example we're going to use annotations to tell `\Phalcon\Mvc\View\Simple` what template must be rendered once the action has been executed:

2.48.4 Annotations Adapters

This component makes use of adapters to cache or no cache the parsed and processed annotations thus improving the performance or providing facilities to development/testing:

Name	Description	API
Memory	The annotations are cached only in memory. When the request ends the cache is cleaned reloading the annotations in each request. This adapter is suitable for a development stage	Phalcon\Annotations\Adapter\Memory
Files	Parsed and processed annotations are stored permanently in PHP files improving performance. This adapter must be used together with a bytecode cache.	Phalcon\Annotations\Adapter\Files
APC	Parsed and processed annotations are stored permanently in the APC cache improving performance. This is the faster adapter	Phalcon\Annotations\Adapter\Apc
XCache	Parsed and processed annotations are stored permanently in the XCache cache improving performance. This is a fast adapter too	Phalcon\Annotations\Adapter\Xcache

Implementing your own adapters

The `Phalcon\Annotations\AdapterInterface` interface must be implemented in order to create your own annotations adapters or extend the existing ones.

2.48.5 External Resources

- Tutorial: Creating a custom model's initializer with Annotations

2.49 Command Line Applications

CLI applications are executed from the command line. They are useful to create cron jobs, scripts, command utilities and more.

2.49.1 Structure

A minimal structure of a CLI application will look like this:

- app/config/config.php
- app/tasks/MainTask.php
- app/cli.php <- main bootstrap file

2.49.2 Creating a Bootstrap

As in regular MVC applications, a bootstrap file is used to bootstrap the application. Instead of the `index.php` bootstrapper in web applications, we use a `cli.php` file for bootstrapping the application.

Below is a sample bootstrap that is being used for this example.

```
<?php

use Phalcon\DI\FactoryDefault\CLI as CliDI,
    Phalcon\CLI\Console as ConsoleApp;

define('VERSION', '1.0.0');

//Using the CLI factory default services container
$di = new CliDI();
```

```
// Define path to application directory
defined('APPLICATION_PATH')
|| define('APPLICATION_PATH', realpath(dirname(__FILE__)));

/**
 * Register the autoloader and tell it to register the tasks directory
 */
$loader = new \Phalcon\Loader();
$loader->registerDirs(
    array(
        APPLICATION_PATH . '/tasks'
    )
);
$loader->register();

// Load the configuration file (if any)
if(is_readable(APPLICATION_PATH . '/config/config.php')) {
    $config = include APPLICATION_PATH . '/config/config.php';
    $di->set('config', $config);
}

//Create a console application
$console = new ConsoleApp();
$console->setDI($di);

/**
 * Process the console arguments
 */
$arguments = array();
foreach($argv as $k => $arg) {
    if($k == 1) {
        $arguments['task'] = $arg;
    } elseif($k == 2) {
        $arguments['action'] = $arg;
    } elseif($k >= 3) {
        $arguments['params'][] = $arg;
    }
}

// define global constants for the current task and action
define('CURRENT_TASK', (isset($argv[1]) ? $argv[1] : null));
define('CURRENT_ACTION', (isset($argv[2]) ? $argv[2] : null));

try {
    // handle incoming arguments
    $console->handle($arguments);
}
catch (\Phalcon\Exception $e) {
    echo $e->getMessage();
    exit(255);
}
```

This piece of code can be run using:

```
$ php app/cli.php
This is the default task and the default action
```

2.49.3 Tasks

Tasks work similar to controllers. Any CLI application needs at least a mainTask and a mainAction and every task needs to have a mainAction which will run if no action is given explicitly.

Below is an example of the app/tasks/MainTask.php file

```
<?php

class MainTask extends \Phalcon\CLI\Task
{
    public function mainAction() {
        echo "\nThis is the default task and the default action \n";
    }
}
```

2.49.4 Processing action parameters

It's possible to pass parameters to actions, the code for this is already present in the sample bootstrap.

If you run the application with the following parameters and action:

```
<?php

class MainTask extends \Phalcon\CLI\Task
{
    public function mainAction() {
        echo "\nThis is the default task and the default action \n";
    }

    /**
     * @param array $params
     */
    public function testAction(array $params) {
        echo sprintf('hello %s', $params[0]) . PHP_EOL;
        echo sprintf('best regards, %s', $params[1]) . PHP_EOL;
    }
}
```

```
$ php app/cli.php main test world universe
hello world
best regards, universe
```

2.49.5 Running tasks in a chain

It's also possible to run tasks in a chain if it's required. To accomplish this you must add the console itself to the DI:

```
<?php

$di->setShared('console', $console);

try {
    // handle incoming arguments
    $console->handle($arguments);
}
```

Then you can use the console inside of any task. Below is an example of a modified MainTask.php:

```
<?php

class MainTask extends \Phalcon\CLI\Task
{
    public function mainAction() {
        echo "\nThis is the default task and the default action \n";

        $this->console->handle(array(
            'task' => 'main',
            'action' => 'test'
        ));
    }

    public function testAction() {
        echo '\nI will get printed too!\n';
    }
}
```

However, it's a better idea to extend \Phalcon\CLI\Task and implement this kind of logic there.

2.50 Queueing

Perform activities like process a video, resize images or send emails aren't suitable to be executed online or in real time because it may slow the loading time of pages, impacting the user experience.

The best solution here is implementing background jobs. A web application must put the job into a queue and wait that it will be processed.

While you can find more sophisticated PHP extensions to address queueing in your applications like [RabbitMQ](#); Phalcon provides a client for [Beanstalk](#), a job queueing backend inspired by [Memcache](#). It's simple, lightweight, and completely specialized on job queueing.

2.50.1 Putting Jobs into the Queue

After connecting to Bens can insert as many jobs as required. The developer can define the message structure according to the needs of the application:

```
<?php

//Connect to the queue
$queue = new Phalcon\Queue\Beanstalk(array(
    'host' => '192.168.0.21'
));

//Insert the job in the queue
$queue->put(array('processVideo' => 4871));
```

Available connection options are:

Option	Description	Default
host	IP where the beanstalk server is located	127.0.0.1
port	Connection port	11300

In the above example we stored a message which will allow a background job to process a video. The message is stored in the queue immediately and does not have a certain time to life.

Additional options as time to run, priority and delay could be passed as second parameter:

```
<?php

//Insert the job in the queue with options
$queue->put(
    array('processVideo' => 4871),
    array('priority' => 250, 'delay' => 10, 'ttr' => 3600)
);
```

The following options are available:

Op-tion	Description
pri-ority	It's an integer < 2**32. Jobs with smaller priority values will be scheduled before jobs with larger priorities. The most urgent priority is 0; the least urgent priority is 4,294,967,295.
de-lay	It's an integer number of seconds to wait before putting the job in the ready queue. The job will be in the "delayed" state during this time.
ttr	Time to run – is an integer number of seconds to allow a worker to run this job. This time is counted from the moment a worker reserves this job.

Every job put into the queue returns a “job id” the developer can use to track the status of the job:

```
<?php

$jobId = $queue->put(array('processVideo' => 4871));
```

2.50.2 Retrieving Messages

Once a job is placed into the queue, those messages can be consumed by a background job which have enough time to complete the task:

```
<?php

while (($job = $queue->peekReady()) !== false) {
    $message = $job->getBody();
    var_dump($message);
    $job->delete();
}
```

Jobs must be removed from the queue to avoid double processing. If multiple background jobs workers are implemented, jobs must be “reserved” so other workers don't re-process them while other workers have them reserved:

```
<?php

while (($job = $queue->reserve())) {
    $message = $job->getBody();
    var_dump($message);
    $job->delete();
}
```

Our client implement a basic set of the features provided by Beanstalkd but enough to allow you to build applications implementing queues.

2.51 Database Abstraction Layer

Phalcon\Db is the component behind Phalcon\Mvc\Model that powers the model layer in the framework. It consists of an independent high-level abstraction layer for database systems completely written in C.

This component allows for a lower level database manipulation than using traditional models.

This guide is not intended to be a complete documentation of available methods and their arguments. Please visit the [API](#) for a complete reference.

2.51.1 Database Adapters

This component makes use of adapters to encapsulate specific database system details. Phalcon uses PDO to connect to databases. The following database engines are supported:

Name	Description	API
MySQL	Is the world's most used relational database management system (RDBMS) that runs as a server providing multi-user access to a number of databases	Phalcon\Db\Adapter\Pdo\Mysql
PostgreSQL	PostgreSQL is a powerful, open source relational database system. It has more than 15 years of active development and a proven architecture that has earned it a strong reputation for reliability, data integrity, and correctness.	Phalcon\Db\Adapter\Pdo\Postgresql
SQLite	SQLite is a software library that implements a self-contained, serverless, zero-configuration, transactional SQL database engine	Phalcon\Db\Adapter\Pdo\Sqlite
Oracle	Oracle is an object-relational database management system produced and marketed by Oracle Corporation.	Phalcon\Db\Adapter\Pdo\Oracle

Implementing your own adapters

The [Phalcon\Db\AdapterInterface](#) interface must be implemented in order to create your own database adapters or extend the existing ones.

2.51.2 Database Dialects

Phalcon encapsulates the specific details of each database engine in dialects. Those provide common functions and SQL generator to the adapters.

Name	Description	API
MySQL	SQL specific dialect for MySQL database system	Phalcon\Db\Dialect\Mysql
PostgreSQL	SQL specific dialect for PostgreSQL database system	Phalcon\Db\Dialect\Postgresql
SQLite	SQL specific dialect for SQLite database system	Phalcon\Db\Dialect\Sqlite
Oracle	SQL specific dialect for Oracle database system	Phalcon\Db\Dialect\Oracle

Implementing your own dialects

The [Phalcon\Db\DialectInterface](#) interface must be implemented in order to create your own database dialects or extend the existing ones.

2.51.3 Connecting to Databases

To create a connection it's necessary instantiate the adapter class. It only requires an array with the connection parameters. The example below shows how to create a connection passing both required and optional parameters:

```
<?php

// Required
$config = array(
    "host" => "127.0.0.1",
    "username" => "mike",
    "password" => "sigma",
    "dbname" => "test_db"
);

// Optional
$config["persistent"] = false;

// Create a connection
$connection = new \Phalcon\Db\Adapter\Pdo\Mysql($config);
```

```
<?php

// Required
$config = array(
    "host" => "localhost",
    "username" => "postgres",
    "password" => "secret1",
    "dbname" => "template"
);

// Optional
$config["schema"] = "public";

// Create a connection
$connection = new \Phalcon\Db\Adapter\Pdo\Postgresql($config);
```

```
<?php

// Required
$config = array(
    "dbname" => "/path/to/database.db"
);

// Create a connection
$connection = new \Phalcon\Db\Adapter\Pdo\Sqlite($config);
```

```
<?php

// Basic configuration
$config = array(
    'username' => 'scott',
    'password' => 'tiger',
    'dbname' => '192.168.10.145/orcl',
);

// Advanced configuration
$config = array(
```

```
'dbname' => '(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP) (HOST=localhost) (PORT=1521))) (CONN  
'username' => 'scott',  
'password' => 'tiger',  
'charset' => 'AL32UTF8',  
);  
  
// Create a connection  
$connection = new \Phalcon\Db\Adapter\Pdo\Oracle($config);
```

2.51.4 Setting up additional PDO options

You can set PDO options at connection time by passing the parameters ‘options’:

```
<?php  
  
// Create a connection with PDO options  
$connection = new \Phalcon\Db\Adapter\Pdo\Mysql(array(  
    "host" => "localhost",  
    "username" => "root",  
    "password" => "sigma",  
    "dbname" => "test_db",  
    "options" => array(  
        PDO::MYSQL_ATTR_INIT_COMMAND => "SET NAMES \\'UTF8\\\'",  
        PDO::ATTR_CASE => PDO::CASE_LOWER  
    )  
));
```

2.51.5 Finding Rows

Phalcon\Db provides several methods to query rows from tables. The specific SQL syntax of the target database engine is required in this case:

```
<?php  
  
$sql = "SELECT id, name FROM robots ORDER BY name";  
  
// Send a SQL statement to the database system  
$result = $connection->query($sql);  
  
// Print each robot name  
while ($robot = $result->fetch()) {  
    echo $robot["name"];  
}  
  
// Get all rows in an array  
$robots = $connection->fetchAll($sql);  
foreach ($robots as $robot) {  
    echo $robot["name"];  
}  
  
// Get only the first row  
$robot = $connection->fetchOne($sql);
```

By default these calls create arrays with both associative and numeric indexes. You can change this behavior by using Phalcon\Db\Result::setFetchMode(). This method receives a constant, defining which kind of index is required.

Constant	Description
Phalcon\Db::FETCH_NUM	Return an array with numeric indexes
Phalcon\Db::FETCH_ASSOC	Return an array with associative indexes
Phalcon\Db::FETCH_BOTH	Return an array with both associative and numeric indexes
Phalcon\Db::FETCH_OBJ	Return an object instead of an array

```
<?php

$sql = "SELECT id, name FROM robots ORDER BY name";
$result = $connection->query($sql);

$result->setFetchMode(Phalcon\Db::FETCH_NUM);
while ($robot = $result->fetch()) {
    echo $robot[0];
}
```

The Phalcon\Db::query() returns an instance of `Phalcon\Db\Result\Pdo`. These objects encapsulate all the functionality related to the returned resultset i.e. traversing, seeking specific records, count etc.

```
<?php

$sql = "SELECT id, name FROM robots";
$result = $connection->query($sql);

// Traverse the resultset
while ($robot = $result->fetch()) {
    echo $robot["name"];
}

// Seek to the third row
$result->seek(2);
$robot = $result->fetch();

// Count the resultset
echo $result->numRows();
```

2.51.6 Binding Parameters

Bound parameters is also supported in `Phalcon\Db`. Although there is a minimal performance impact by using bound parameters, you are encouraged to use this methodology so as to eliminate the possibility of your code being subject to SQL injection attacks. Both string and positional placeholders are supported. Binding parameters can simply be achieved as follows:

```
<?php

// Binding with numeric placeholders
$sql     = "SELECT * FROM robots WHERE name = ? ORDER BY name";
$result = $connection->query($sql, array("Wall-E"));

// Binding with named placeholders
$sql     = "INSERT INTO `robots`(`name`, `year`) VALUES (:name, :year)";
$success = $connection->query($sql, array("name" => "Astro Boy", "year" => 1952));
```

2.51.7 Inserting/Updating/Deleting Rows

To insert, update or delete rows, you can use raw SQL or use the preset functions provided by the class:

```
<?php

// Inserting data with a raw SQL statement
$sql      = "INSERT INTO `robots`(`name`, `year`) VALUES ('Astro Boy', 1952)";
$success = $connection->execute($sql);

//With placeholders
$sql      = "INSERT INTO `robots`(`name`, `year`) VALUES (?, ?)";
$success = $connection->execute($sql, array('Astro Boy', 1952));

// Generating dynamically the necessary SQL
$success = $connection->insert(
    "robots",
    array("Astro Boy", 1952),
    array("name", "year")
);

// Generating dynamically the necessary SQL (another syntax)
$success = $connection->insertAsDict(
    "robots",
    array(
        "name" => "Astro Boy",
        "year" => 1952
    )
);

// Updating data with a raw SQL statement
$sql      = "UPDATE `robots` SET `name` = 'Astro boy' WHERE `id` = 101";
$success = $connection->execute($sql);

//With placeholders
$sql      = "UPDATE `robots` SET `name` = ? WHERE `id` = ?";
$success = $connection->execute($sql, array('Astro Boy', 101));

// Generating dynamically the necessary SQL
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    "id = 101" //Warning! In this case values are not escaped
);

// Generating dynamically the necessary SQL (another syntax)
$success = $connection->updateAsDict(
    "robots",
    array(
        "name" => "New Astro Boy"
    ),
    "id = 101" //Warning! In this case values are not escaped
);

//With escaping conditions
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    array(
        'conditions' => 'id = ?',
        'values' => array(101)
    )
);
```

```

        'bind' => array(101),
        'bindTypes' => array(PDO::PARAM_INT) //optional parameter
    )
);

$success = $connection->updateAsDict(
    "robots",
    array(
        "name" => "New Astro Boy"
    ),
    array(
        'conditions' => 'id = ?',
        'bind' => array(101),
        'bindTypes' => array(PDO::PARAM_INT) //optional parameter
    )
);

// Deleting data with a raw SQL statement
$sql      = "DELETE `robots` WHERE `id` = 101";
$success = $connection->execute($sql);

//With placeholders
$sql      = "DELETE `robots` WHERE `id` = ?";
$success = $connection->execute($sql, array(101));

// Generating dynamically the necessary SQL
$success = $connection->delete("robots", "id = ?", array(101));

```

2.51.8 Transactions and Nested Transactions

Working with transactions is supported as it is with PDO. Perform data manipulation inside transactions often increase the performance on most database systems:

```

<?php

try {

    // Start a transaction
    $connection->begin();

    // Execute some SQL statements
    $connection->execute("DELETE `robots` WHERE `id` = 101");
    $connection->execute("DELETE `robots` WHERE `id` = 102");
    $connection->execute("DELETE `robots` WHERE `id` = 103");

    // Commit if everything goes well
    $connection->commit();

} catch(Exception $e) {
    // An exception has occurred rollback the transaction
    $connection->rollback();
}

```

In addition to standard transactions, Phalcon\Db provides built-in support for [nested transactions](#) (if the database system used supports them). When you call begin() for a second time a nested transaction is created:

```
<?php
```

```
try {

    // Start a transaction
    $connection->begin();

    // Execute some SQL statements
    $connection->execute("DELETE `robots` WHERE `id` = 101");

    try {

        //Start a nested transaction
        $connection->begin();

        //Execute these SQL statements into the nested transaction
        $connection->execute("DELETE `robots` WHERE `id` = 102");
        $connection->execute("DELETE `robots` WHERE `id` = 103");

        //Create a save point
        $connection->commit();

    } catch(Exception $e) {
        //An error has occurred, release the nested transaction
        $connection->rollback();
    }

    //Continue, executing more SQL statements
    $connection->execute("DELETE `robots` WHERE `id` = 104");

    //Commit if everything goes well
    $connection->commit();

} catch(Exception $e) {
    //An exception has occurred rollback the transaction
    $connection->rollback();
}
```

2.51.9 Database Events

Phalcon\Db is able to send events to a [EventManager](#) if it's present. Some events when returning boolean false could stop the active operation. The following events are supported:

Event Name	Triggered	Can stop operation?
afterConnect	After a successfully connection to a database system	No
beforeQuery	Before send a SQL statement to the database system	Yes
afterQuery	After send a SQL statement to database system	No
beforeDisconnect	Before close a temporal database connection	No
beginTransaction	Before a transaction is going to be started	No
rollbackTransaction	Before a transaction is rollbacked	No
commitTransaction	Before a transaction is committed No	

Bind an [EventManager](#) to a connection is simple, Phalcon\Db will trigger the events with the type "db":

```
<?php

use Phalcon\Events\Manager as EventsManager,
\Phalcon\Db\Adapter\Pdo\Mysql as Connection;
```

```
$eventsManager = new EventsManager();

//Listen all the database events
$eventsManager->attach('db', $dbListener);

$connection = new Connection(array(
    "host" => "localhost",
    "username" => "root",
    "password" => "secret",
    "dbname" => "invo"
));

//Assign the eventsManager to the db adapter instance
$connection->setEventsManager($eventsManager);
```

Stop SQL operations are very useful if for example you want to implement some last-resource SQL injector checker:

```
<?php

$eventsManager->attach('db:beforeQuery', function($event, $connection) {

    //Check for malicious words in SQL statements
    if (preg_match('/DROP|ALTER/i', $connection->getSQLStatement())) {
        // DROP/ALTER operations aren't allowed in the application,
        // this must be a SQL injection!
        return false;
    }

    //It's ok
    return true;
});
```

2.51.10 Profiling SQL Statements

Phalcon\Db includes a profiling component called **Phalcon\Db\Profiler**, that is used to analyze the performance of database operations so as to diagnose performance problems and discover bottlenecks.

Database profiling is really easy With Phalcon\Db\Profiler:

```
<?php

use Phalcon\Events\Manager as EventsManager,
    Phalcon\Db\Profiler as DbProfiler;

$eventsManager = new EventsManager();

$profiler = new DbProfiler();

// Listen all the database events
$eventsManager->attach('db', function($event, $connection) use ($profiler) {
    if ($event->getType() == 'beforeQuery') {
        // Start a profile with the active connection
        $profiler->startProfile($connection->getSQLStatement());
    }
    if ($event->getType() == 'afterQuery') {
        // Stop the active profile
        $profiler->stopProfile();
    }
});
```

```
    }

});

// Assign the events manager to the connection
$connection->setEventsManager($eventsManager);

$sql = "SELECT buyer_name, quantity, product_name "
    . "FROM buyers "
    . "LEFT JOIN products ON buyers.pid = products.id";

// Execute a SQL statement
$connection->query($sql);

// Get the last profile in the profiler
$profile = $profiler->getLastProfile();

echo "SQL Statement: ", $profile->getSQLStatement(), "\n";
echo "Start Time: ", $profile->getInitialTime(), "\n";
echo "Final Time: ", $profile->getFinalTime(), "\n";
echo "Total Elapsed Time: ", $profile->getTotalElapsedSeconds(), "\n";
```

You can also create your own profile class based on [Phalcon\Db\Profiler](#) to record real time statistics of the statements sent to the database system:

```
<?php

use Phalcon\Events\Manager as EventsManager,
    Phalcon\Db\Profiler as Profiler,
    Phalcon\Db\Profiler\Item as Item;

class DbProfiler extends Profiler
{

    /**
     * Executed before the SQL statement will sent to the db server
     */
    public function beforeStartProfile(Item $profile)
    {
        echo $profile->getSQLStatement();
    }

    /**
     * Executed after the SQL statement was sent to the db server
     */
    public function afterEndProfile(Item $profile)
    {
        echo $profile->getTotalElapsedSeconds();
    }

}

//Create an EventsManager
$eventsManager = new EventsManager();

//Create a listener
$dbProfiler = new DbProfiler();

//Attach the listener listening for all database events
```

```
$eventsManager->attach('db', $dbProfiler);
```

2.51.11 Logging SQL Statements

Using high-level abstraction components such as `Phalcon\Db` to access a database, it is difficult to understand which statements are sent to the database system. `Phalcon\Logger` interacts with `Phalcon\Db`, providing logging capabilities on the database abstraction layer.

```
<?php

use Phalcon\Logger,
    Phalcon\Events\Manager as EventsManager,
    Phalcon\Logger\Adapter\File as FileLogger;

$eventsManager = new EventsManager();

$logger = new FileLogger("app/logs/db.log");

// Listen all the database events
$eventsManager->attach('db', function($event, $connection) use ($logger) {
    if ($event->getType() == 'beforeQuery') {
        $logger->log($connection->getSQLStatement(), Logger::INFO);
    }
});

// Assign the eventsManager to the db adapter instance
$connection->setEventsManager($eventsManager);

// Execute some SQL statement
$connection->insert(
    "products",
    array("Hot pepper", 3.50),
    array("name", "price")
);
```

As above, the file `app/logs/db.log` will contain something like this:

```
[Sun, 29 Apr 12 22:35:26 -0500] [DEBUG] [Resource Id #77] INSERT INTO products
(name, price) VALUES ('Hot pepper', 3.50)
```

Implementing your own Logger

You can implement your own logger class for database queries, by creating a class that implements a single method called “log”. The method needs to accept a string as the first argument. You can then pass your logging object to `Phalcon\Db::setLogger()`, and from then on any SQL statement executed will call that method to log the results.

2.51.12 Describing Tables/Views

`Phalcon\Db` also provides methods to retrieve detailed information about tables and views:

```
<?php

// Get tables on the test_db database
$tables = $connection->listTables("test_db");
```

```
// Is there a table 'robots' in the database?
$exists = $connection->tableExists("robots");

// Get name, data types and special features of 'robots' fields
$fields = $connection->describeColumns("robots");
foreach ($fields as $field) {
    echo "Column Type: ", $field["Type"];
}

// Get indexes on the 'robots' table
$indexes = $connection->describeIndexes("robots");
foreach ($indexes as $index) {
    print_r($index->getColumns());
}

// Get foreign keys on the 'robots' table
$references = $connection->describeReferences("robots");
foreach ($references as $reference) {
    // Print referenced columns
    print_r($reference->getReferencedColumns());
}
```

A table description is very similar to the MySQL describe command, it contains the following information:

Index	Description
Field	Field's name
Type	Column Type
Key	Is the column part of the primary key or an index?
Null	Does the column allow null values?

Methods to get information about views are also implemented for every supported database system:

```
<?php

// Get views on the test_db database
$tables = $connection->listViews("test_db");

// Is there a view 'robots' in the database?
$exists = $connection->viewExists("robots");
```

2.51.13 Creating/Altering/Dropping Tables

Different database systems (MySQL, Postgresql etc.) offer the ability to create, alter or drop tables with the use of commands such as CREATE, ALTER or DROP. The SQL syntax differs based on which database system is used. Phalcon\Db offers a unified interface to alter tables, without the need to differentiate the SQL syntax based on the target storage system.

Creating Tables

The following example shows how to create a table:

```
<?php

use \Phalcon\Db\Column as Column;

$connection->createTable(
```

```

"robots",
null,
array(
    "columns" => array(
        new Column("id",
            array(
                "type"      => Column::TYPE_INTEGER,
                "size"      => 10,
                "notNull"   => true,
                "autoIncrement" => true,
            )
        ),
        new Column("name",
            array(
                "type"      => Column::TYPE_VARCHAR,
                "size"      => 70,
                "notNull"   => true,
            )
        ),
        new Column("year",
            array(
                "type"      => Column::TYPE_INTEGER,
                "size"      => 11,
                "notNull"   => true,
            )
        )
    )
)
);

```

Phalcon\Db::createTable() accepts an associative array describing the table. Columns are defined with the class [Phalcon\Db\Column](#). The table below shows the options available to define a column:

Option	Description	Op-tional
“type”	Column type. Must be a Phalcon\Db\Column constant (see below for a list)	No
“primary”	True if the column is part of the table’s primary	Yes
“size”	Some type of columns like VARCHAR or INTEGER may have a specific size	Yes
“scale”	DECIMAL or NUMBER columns may have a scale to specify how many decimals should be stored	Yes
“un-signed”	INTEGER columns may be signed or unsigned. This option does not apply to other types of columns	Yes
“notNull”	Column can store null values?	Yes
“autoIn-crement”	With this attribute column will be filled automatically with an auto-increment integer. Only one column in the table can have this attribute.	Yes
“bind”	One of the BIND_TYPE_* constants telling how the column must be binded before save it	Yes
“first”	Column must be placed at first position in the column order	Yes
“after”	Column must be placed after indicated column	Yes

Phalcon\Db supports the following database column types:

- Phalcon\Db\Column::TYPE_INTEGER
- Phalcon\Db\Column::TYPE_DATE
- Phalcon\Db\Column::TYPE_VARCHAR
- Phalcon\Db\Column::TYPE_DECIMAL

- Phalcon\Db\Column::TYPE_DATETIME
- Phalcon\Db\Column::TYPE_CHAR
- Phalcon\Db\Column::TYPE_TEXT

The associative array passed in Phalcon\Db::createTable() can have the possible keys:

Index	Description	Op-tional
“columns”	An array with a set of table columns defined with Phalcon\Db\Column	No
“in-dexes”	An array with a set of table indexes defined with Phalcon\Db\Index	Yes
“refer-ences”	An array with a set of table references (foreign keys) defined with Phalcon\Db\Reference	Yes
“op-tions”	An array with a set of table creation options. These options often relate to the database system in which the migration was generated.	Yes

Altering Tables

As your application grows, you might need to alter your database, as part of a refactoring or adding new features. Not all database systems allow to modify existing columns or add columns between two existing ones. Phalcon\Db is limited by these constraints.

```
<?php

use Phalcon\Db\Column as Column;

// Adding a new column
$connection->addColumn("robots", null,
    new Column("robot_type", array(
        "type"      => Column::TYPE_VARCHAR,
        "size"      => 32,
        "notNull"   => true,
        "after"     => "name"
    )));
;

// Modifying an existing column
$connection->modifyColumn("robots", null, new Column("name", array(
    "type"      => Column::TYPE_VARCHAR,
    "size"      => 40,
    "notNull"   => true,
)));
;

// Deleting the column "name"
$connection->dropColumn("robots", null, "name");
;
```

Dropping Tables

Examples on dropping tables:

```
<?php

// Drop table robot from active database
$connection->dropTable("robots");
;
```

```
//Drop table robot from database "machines"
$connection->dropTable("robots", "machines");
```

2.52 Internationalization

Phalcon is written in C as an extension for PHP. There is a PECL extension that offers internationalization functions to PHP applications called [intl](#). Starting from PHP 5.4/5.5 this extension is bundled with PHP. Its documentation can be found in the pages of the official [PHP manual](#).

Phalcon does not offer this functionality, since creating such a component would be replicating existing code.

In the examples below, we will show you how to implement the [intl](#) extension's functionality into Phalcon powered applications.

This guide is not intended to be a complete documentation of the [intl](#) extension. Please visit its the [documentation](#) of the extension for a reference.

2.52.1 Find out best available Locale

There are several ways to find out the best available locale using [intl](#). One of them is to check the HTTP “Accept-Language” header:

```
<?php

$locale = Locale::acceptFromHttp($_SERVER["HTTP_ACCEPT_LANGUAGE"]);

// Locale could be something like "en_GB" or "en"
echo $locale;
```

Below method returns a locale identified. It is used to get language, culture, or regionally-specific behavior from the Locale API. Examples of identifiers include:

- en-US (English, United States)
- zh-Hant-TW (Chinese, Traditional Script, Taiwan)
- fr-CA, fr-FR (French for Canada and France respectively)

2.52.2 Formatting messages based on Locale

Part of creating a localized application is to produce concatenated, language-neutral messages. The MessageFormatter allows for the production of those messages.

Printing numbers formatted based on some locale:

```
<?php

// Prints € 4 560
$formatter = new MessageFormatter("fr_FR", "€ {0, number, integer}");
echo $formatter->format(array(4560));

// Prints USD$ 4,560.5
$formatter = new MessageFormatter("en_US", "USD$ {0, number}");
echo $formatter->format(array(4560.5));

// Prints ARS$ 1.250,25
```

```
$formatter = new MessageFormatter("es_AR", "ARS$ {0, number}");
echo $formatter->format(array(1250.25));
```

Message formatting using time and date patterns:

```
<?php

//Setting parameters
$time   = time();
$values = array(7, $time, $time);

// Prints "At 3:50:31 PM on Apr 19, 2012, there was a disturbance on planet 7."
$pattern  = "At {1, time} on {1, date}, there was a disturbance on planet {0, number}.";
$formatter = new MessageFormatter("en_US", $pattern);
echo $formatter->format($values);

// Prints "À 15:53:01 le 19 avr. 2012, il y avait une perturbation sur la planète 7."
$pattern  = "À {1, time} le {1, date}, il y avait une perturbation sur la planète {0, number}.";
$formatter = new MessageFormatter("fr_FR", $pattern);
echo $formatter->format($values);
```

2.52.3 Locale-Sensitive comparison

The `Collator` class provides string comparison capability with support for appropriate locale-sensitive sort orderings. Check the examples below on the usage of this class:

```
<?php

// Create a collator using Spanish locale
$collator = new Collator("es");

// Returns that the strings are equal, in spite of the emphasis on the "o"
$collator->setStrength(Collator::PRIMARY);
var_dump($collator->compare("una canción", "una cancion"));

// Returns that the strings are not equal
$collator->setStrength(Collator::DEFAULT_VALUE);
var_dump($collator->compare("una canción", "una cancion"));
```

2.52.4 Transliteration

Transliterator provides transliteration of strings:

```
<?php

$id = "Any-Latin; NFD; [:Nonspacing Mark:] Remove; NFC; [:Punctuation:] Remove; Lower();";
$transliterator = Transliterator::create($id);

$string = "garçon-étudiant-ou-L'école";
echo $transliterator->transliterate($string); // garconetudiantoulecole
```

2.53 Database Migrations

Migrations are a convenient way for you to alter your database in a structured and organized manner.

Important: Migrations are available on [Phalcon Developer Tools](#). You need at least Phalcon Framework version 0.5.0 to use developer tools. Also is recommended to have PHP 5.4 or greater installed.

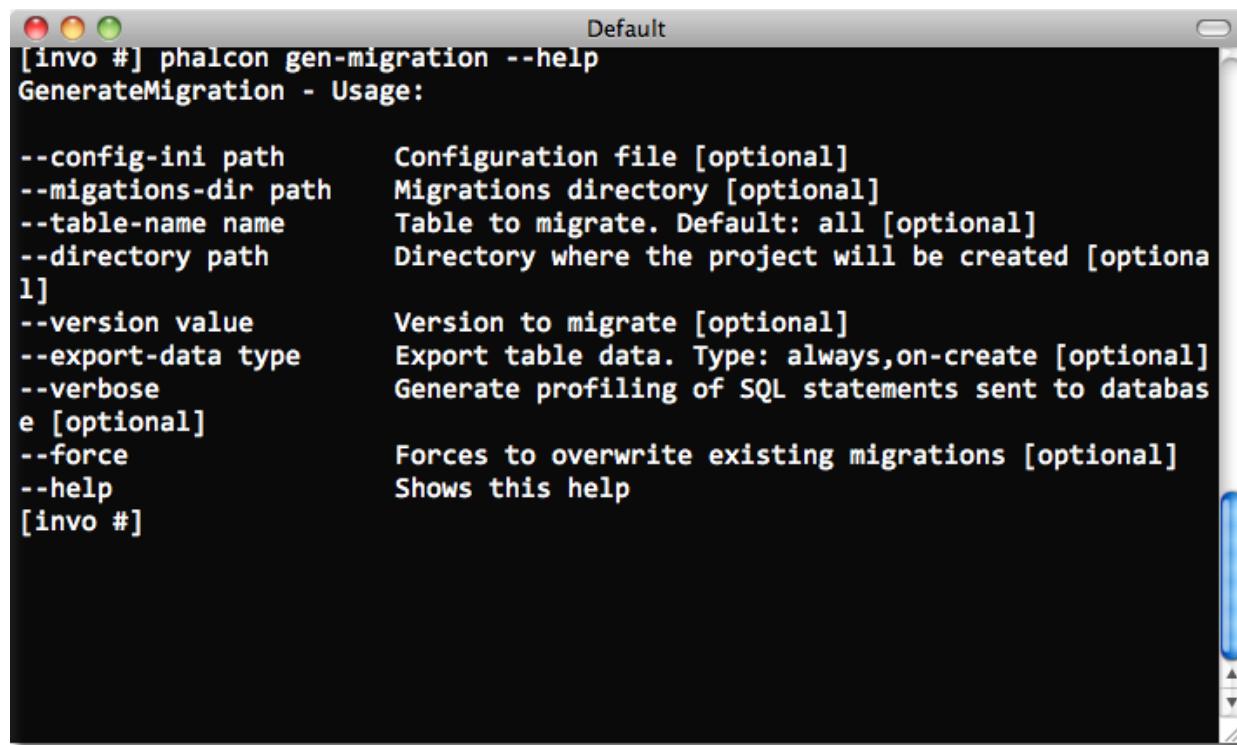

Often in development we need to update changes in production environments. Some of these changes could be database modifications like new fields, new tables, removing indexes, etc.

When a migration is generated a set of classes are created to describe how your database is structured at that moment. These classes can be used to synchronize the schema structure on remote databases setting your database ready to work with the new changes that your application implements. Migrations describe these transformations using plain PHP.

2.53.1 Schema Dumping

The [Phalcon Developer Tools](#) provides scripts to manage migrations (generation, running and rollback).

The available options for generating migrations are:

```
Default
[invo #] phalcon gen-migration --help
GenerateMigration - Usage:

--config-ini path      Configuration file [optional]
--migrations-dir path  Migrations directory [optional]
--table-name name      Table to migrate. Default: all [optional]
--directory path        Directory where the project will be created [optional]
--version value         Version to migrate [optional]
--export-data type     Export table data. Type: always,on-create [optional]
--verbose               Generate profiling of SQL statements sent to database
--force                 Forces to overwrite existing migrations [optional]
--help                  Shows this help
[invo #]
```

Running this script without any parameters will simply dump every object (tables and views) from your database in migration classes.

Each migration has a version identifier associated to it. The version number allows us to identify if the migration is newer or older than the current ‘version’ of our database. Versions also inform Phalcon of the running order when executing a migration.

When a migration is generated, instructions are displayed on the console to describe the different steps of the migration and the execution time of those statements. At the end, a migration version is generated.

By default [Phalcon Developer Tools](#) use the *app/migrations* directory to dump the migration files. You can change the location by setting one of the parameters on the generation script. Each table in the database has its respective class generated in a separated file under a directory referring its version:

```
Default
T, TABLES.ENGINE, TABLES.TABLE_COLLATION FROM INFORMATION_SCHEMA
.TABLES WHERE TABLES.TABLE_SCHEMA = "invo" AND TABLES.TABLE_NA
ME = "test" => 1335920161.9368 (0.00032401084899902)
1335920161.9369: DESCRIBE `invo`.`users` => 1335920161.938 (0
.0010280609130859)
1335920161.9383: SHOW INDEXES FROM `invo`.`users` => 13359201
61.9389 (0.00062680244445801)
1335920161.939: SELECT TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME,
REFERENCED_TABLE_SCHEMA, REFERENCED_TABLE_NAME, REFERENCED_COLU
N_NAME FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE WHERE REFER
ENCED_TABLE_NAME IS NOT NULL AND CONSTRAINT_SCHEMA = "invo" AN
D TABLE_NAME = "users" => 1335920161.9403 (0.0012459754943848
)
1335920161.9404: SELECT TABLES.TABLE_TYPE, TABLES.AUTO_INCREMENT
T, TABLES.ENGINE, TABLES.TABLE_COLLATION FROM INFORMATION_SCHEMA
.TABLES WHERE TABLES.TABLE_SCHEMA = "invo" AND TABLES.TABLE_NA
ME = "users" => 1335920161.9407 (0.00038504600524902)
Version 1.0.0 was successfully generated
[invo #]
```

```
Default
[invo #] cd app/migrations/1.0.0/
[1.0.0 #] ls
companies.php           products.php
contact.php              test.php
product_types.php        users.php
[1.0.0 #] ■
```

2.53.2 Migration Class Anatomy

Each file contains a unique class that extends the Phalcon\\Mvc\\Model\\Migration These classes normally have two methods: up() and down(). Up() performs the migration, while down() rolls it back.

Up() also contains the *magic* method morphTable(). The magic comes when it recognizes the changes needed to synchronize the actual table in the database to the description given.

```
<?php

use Phalcon\Db\Column as Column;
use Phalcon\Db\Index as Index;
use Phalcon\Db\Reference as Reference;

class ProductsMigration_100 extends \Phalcon\Mvc\Model\Migration
{

    public function up()
    {
        $this->morphTable(
            "products",
            array(
                "columns" => array(
                    new Column(
                        "id",
                        array(
                            "type"      => Column::TYPE_INTEGER,
                            "size"      => 10,
                            "unsigned"  => true,
                            "notNull"   => true,
                            "autoIncrement" => true,
                            "first"     => true,
                        )
                    ),
                    new Column(
                        "product_types_id",
                        array(
                            "type"      => Column::TYPE_INTEGER,
                            "size"      => 10,
                            "unsigned"  => true,
                            "notNull"   => true,
                            "after"     => "id",
                        )
                    ),
                    new Column(
                        "name",
                        array(
                            "type"      => Column::TYPE_VARCHAR,
                            "size"      => 70,
                            "notNull"   => true,
                            "after"     => "product_types_id",
                        )
                    ),
                    new Column(
                        "price",
                        array(
                            "type"      => Column::TYPE_DECIMAL,
                            "size"      => 16,
                            "scale"     => 2,
                        )
                    )
                )
            )
        );
    }
}
```

```

        "notNull" => true,
        "after"     => "name",
    )
),
),
"indexes" => array(
    new Index(
        "PRIMARY",
        array("id")
    ),
    new Index(
        "product_types_id",
        array("product_types_id")
    )
),
"references" => array(
    new Reference(
        "products_ibfk_1",
        array(
            "referencedSchema" => "invo",
            "referencedTable"   => "product_types",
            "columns"          => array("product_types_id"),
            "referencedColumns"=> array("id"),
        )
    )
),
"options" => array(
    "TABLE_TYPE"      => "BASE TABLE",
    "ENGINE"          => "InnoDB",
    "TABLE_COLLATION" => "utf8_general_ci",
)
);
}
}

```

The class is called “ProductsMigration_100”. Suffix 100 refers to the version 1.0.0. `morphTable()` receives an associative array with 4 possible sections:

Index	Description	Optional
“columns”	An array with a set of table columns	No
“indexes”	An array with a set of table indexes.	Yes
“references”	An array with a set of table references (foreign keys).	Yes
“options”	An array with a set of table creation options. These options are often related to the database system in which the migration was generated.	Yes

Defining Columns

`Phalcon\Db\Column` is used to define table columns. It encapsulates a wide variety of column related features. Its constructor receives as first parameter the column name and an array describing the column. The following options are available when describing columns:

Option	Description	Op-tional
“type”	Column type. Must be a Phalcon_Db_Column constant (see below)	No
“size”	Some type of columns like VARCHAR or INTEGER may have a specific size	Yes
“scale”	DECIMAL or NUMBER columns may be have a scale to specify how much decimals it must store	Yes
“un-signed”	INTEGER columns may be signed or unsigned. This option does not apply to other types of columns	Yes
“notNull”	Column can store null values?	Yes
“autoIn-crement”	With this attribute column will be filled automatically with an auto-increment integer. Only one column in the table can have this attribute.	Yes
“first”	Column must be placed at first position in the column order	Yes
“after”	Column must be placed after indicated column	Yes

Database migrations support the following database column types:

- `Phalcon\Db\Column::TYPE_INTEGER`
- `Phalcon\Db\Column::TYPE_DATE`
- `Phalcon\Db\Column::TYPE_VARCHAR`
- `Phalcon\Db\Column::TYPE_DECIMAL`
- `Phalcon\Db\Column::TYPE_DATETIME`
- `Phalcon\Db\Column::TYPE_CHAR`
- `Phalcon\Db\Column::TYPE_TEXT`

Defining Indexes

`Phalcon\Db\Index` defines table indexes. An index only requires that you define a name for it and a list of its columns. Note that if any index has the name PRIMARY, Phalcon will create a primary key index in that table.

Defining References

`Phalcon\Db\Reference` defines table references (also called foreign keys). The following options can be used to define a reference:

Index	Description	Op-tional
“refer-encedTable”	It's auto-descriptive. It refers to the name of the referenced table.	No
“columns”	An array with the name of the columns at the table that have the reference	No
“referenced-Columns”	An array with the name of the columns at the referenced table	No
“refer-encedTable”	The referenced table maybe is on another schema or database. This option allows you to define that.	Yes

2.53.3 Writing Migrations

Migrations aren't only designed to “morph” table. A migration is just a regular PHP class so you're not limited to these functions. For example after adding a column you could write code to set the value of that column for existing records. For more details and examples of individual methods, check the [database component](#).

```
<?php

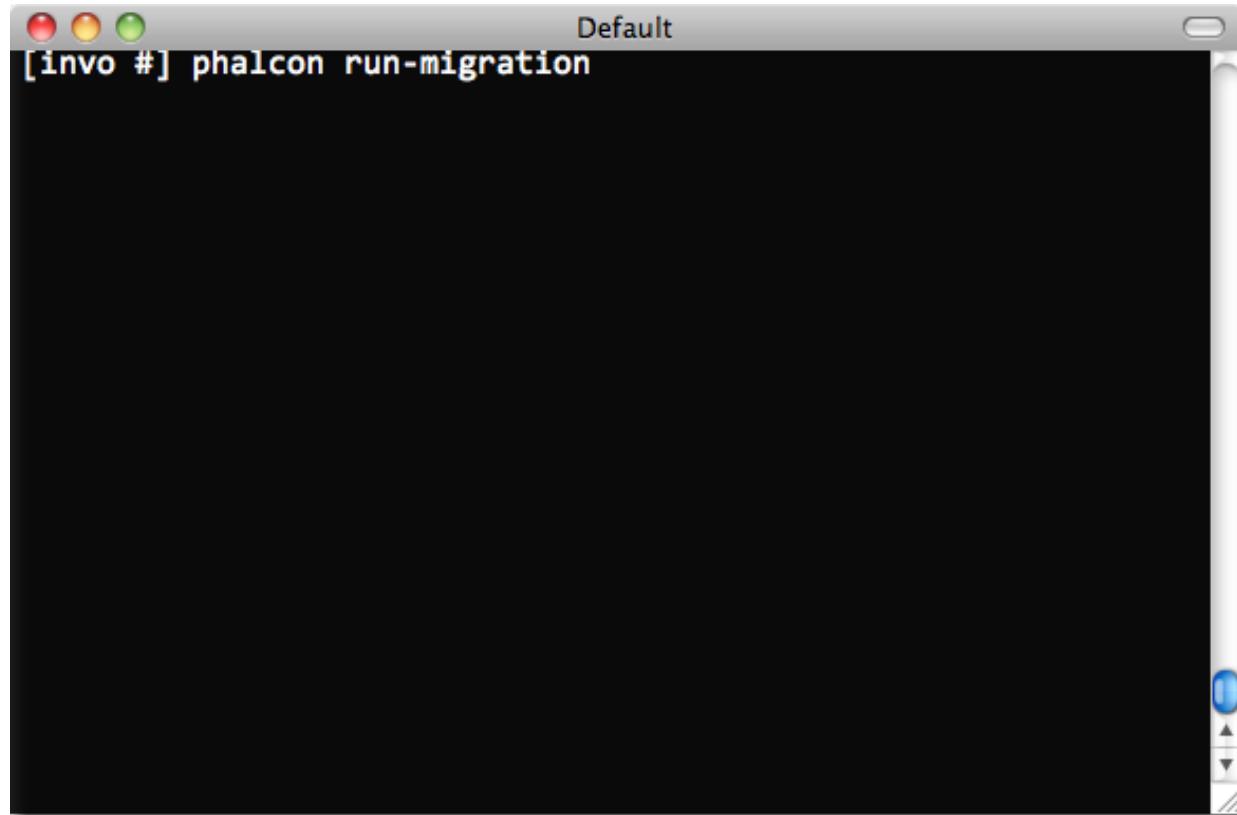

class ProductsMigration_100 extends \Phalcon\Mvc\Model\Migration
{

    public function up()
    {
        //...
        self::$_connection->insert(
            "products",
            array("Malabar spinach", 14.50),
            array("name", "price")
        );
    }

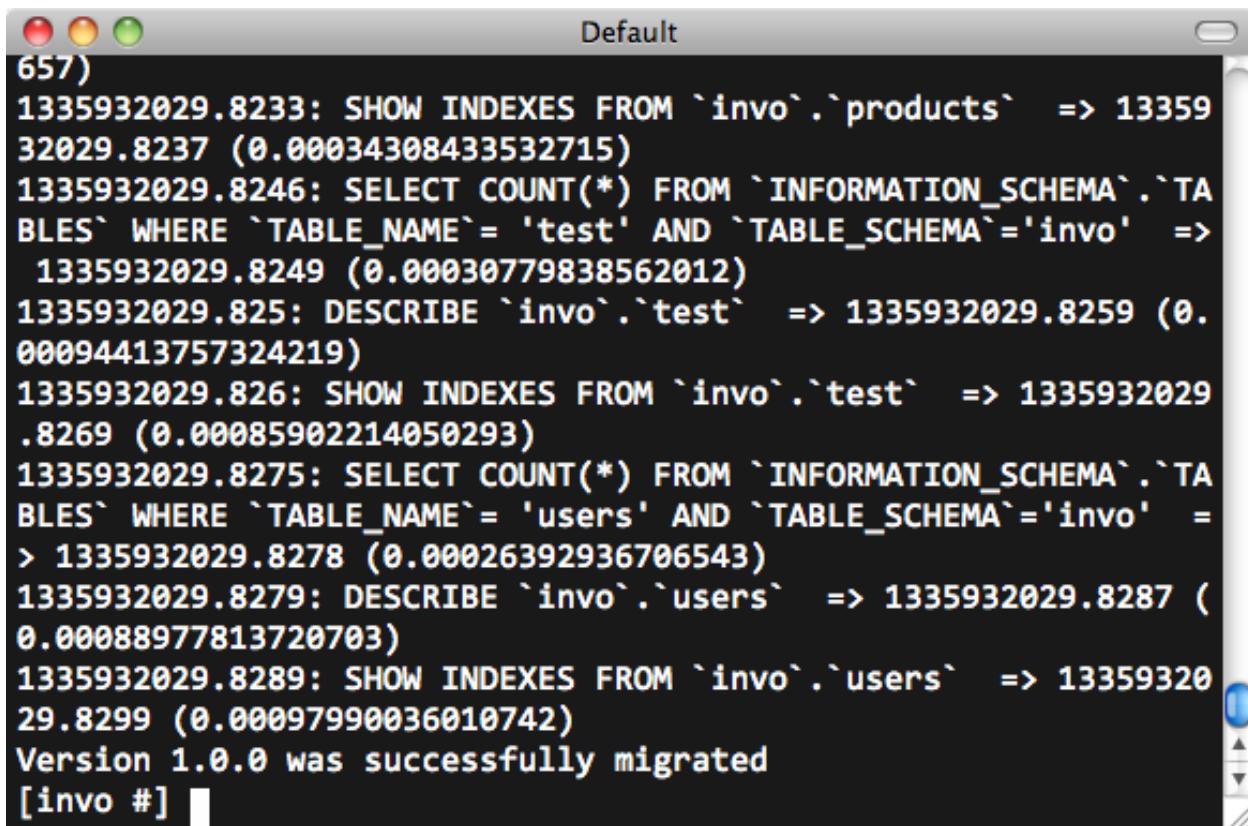

}
```

2.53.4 Running Migrations

Once the generated migrations are uploaded on the target server, you can easily run them as shown in the following example:

Depending on how outdated is the database with respect to migrations, Phalcon may run multiple migration versions in the same migration process. If you specify a target version, Phalcon will run the required migrations until it reaches the specified version.

The screenshot shows a terminal window titled "Default". The output of the terminal is as follows:

```

657)
1335932029.8233: SHOW INDEXES FROM `invo`.`products` => 13359
32029.8237 (0.00034308433532715)
1335932029.8246: SELECT COUNT(*) FROM `INFORMATION_SCHEMA`.`TA
BLES` WHERE `TABLE_NAME` = 'test' AND `TABLE_SCHEMA`='invo' =>
1335932029.8249 (0.00030779838562012)
1335932029.825: DESCRIBE `invo`.`test` => 1335932029.8259 (0.
00094413757324219)
1335932029.826: SHOW INDEXES FROM `invo`.`test` => 1335932029
.8269 (0.00085902214050293)
1335932029.8275: SELECT COUNT(*) FROM `INFORMATION_SCHEMA`.`TA
BLES` WHERE `TABLE_NAME` = 'users' AND `TABLE_SCHEMA`='invo' =>
1335932029.8278 (0.00026392936706543)

```

2.54 Debugging Applications

PHP offers tools to debug applications with notices, warnings, errors and exceptions. The [Exception class](#) offers information such as the file, line, message, numeric code, backtrace etc. on where an error occurred. OOP frameworks like Phalcon mainly use this class to encapsulate this functionality and provide information back to the developer or user.

Despite being written in C, Phalcon executes methods in the PHP userland, providing the debug capability that any other application or framework written in PHP has.

2.54.1 Catching Exceptions

Throughout the tutorials and examples of the Phalcon documentation, there is a common element that is catching exceptions. This is a try/catch block:

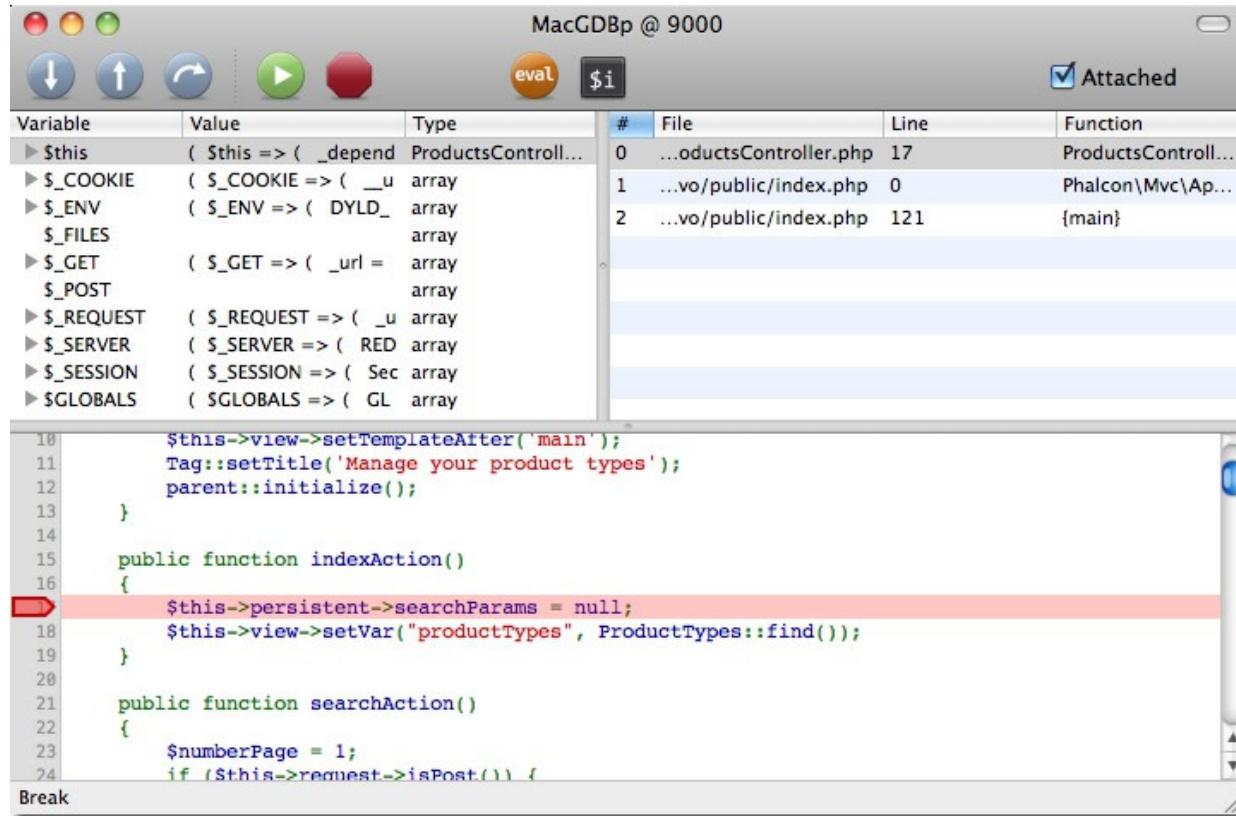

```

<?php

try {
    //... some phalcon/php code
} catch(\Exception $e) {
}

```

Any exception thrown within the block is captured in the variable `$e`. A [Phalcon\Exception](#) extends the PHP [Exception class](#) and is used to understand whether the exception came from Phalcon or PHP itself.

All exceptions generated by PHP are based on the `Exception` class, and have at least the following elements:

```
<?php

class Exception
{

    /* Properties */
    protected string $message;
    protected int $code;
    protected string $file;
    protected int $line;

    /* Methods */
    public __construct ([ string $message = "" [, int $code = 0 [, Exception $previous = NULL ]]])
    final public string getMessage ( void )
    final public Exception getPrevious ( void )
    final public mixed getCode ( void )
    final public string getFile ( void )
    final public int getLine ( void )
    final public array getTrace ( void )
    final public string getTraceAsString ( void )
    public string __toString ( void )
    final private void __clone ( void )
}
```

Retrieving information from `Phalcon\Exception` is the same as PHP's `Exception` class:

```
<?php

try {
    //... app code ...

} catch(\Exception $e) {
    echo get_class($e), ":", $e->getMessage(), "\n";
    echo " File=", $e->getFile(), "\n";
    echo " Line=", $e->getLine(), "\n";
    echo $e->getTraceAsString();
}
```

It's therefore easy to find which file and line of the application's code generated the exception, as well as the components involved in generating the exception:

```
PDOException: SQLSTATE[28000] [1045] Access denied for user 'root'@'localhost'
    (using password: NO)
File=/Applications/MAMP/htdocs/invo/public/index.php
Line=74
#0 [internal function]: PDO->__construct('mysql:host=loca...', 'root', '', Array)
#1 [internal function]: Phalcon\Db\Adapter\Pdo->connect(Array)
#2 /Applications/MAMP/htdocs/invo/public/index.php(74):
    Phalcon\Db\Adapter\Pdo->__construct(Array)
#3 [internal function]: {closure}()
#4 [internal function]: call_user_func_array(Object(Closure), Array)
#5 [internal function]: Phalcon\DI->_factory(Object(Closure), Array)
#6 [internal function]: Phalcon\DI->get('db', Array)
#7 [internal function]: Phalcon\DI->getShared('db')
#8 [internal function]: Phalcon\Mvc\Model->getConnection()
#9 [internal function]: Phalcon\Mvc\Model::__getOrCreateResultset('Users', Array, true)
#10 /Applications/MAMP/htdocs/invo/app/controllers/SessionController.php(83):
    Phalcon\Mvc\Model::__findFirst('email='demo@pha...')
#11 [internal function]: SessionController->startAction()
#12 [internal function]: call_user_func_array(Array, Array)
#13 [internal function]: Phalcon\Mvc\Dispatcher->dispatch()
#14 /Applications/MAMP/htdocs/invo/public/index.php(114): Phalcon\Mvc\Application->handle()
#15 {main}
```

As you can see from the above output the Phalcon's classes and methods are displayed just like any other component, and even showing the parameters that were invoked in every call. The method `Exception::getTrace` provides additional information if needed.

2.54.2 Debug component

Phalcon provides a debug component that allows the developer to easily find errors produced in an application created with the framework.

The following screencast explains how it works:

To enable it, add the following to your bootstrap:

```
<?php

$debug = new \Phalcon\Debug();
$debug->listen();
```

Any Try/Catch blocks must be removed or disabled to make this component work properly.

2.54.3 Reflection and Introspection

Any instance of a Phalcon class offers exactly the same behavior than a PHP normal one. It's possible to use the [Reflection API](#) or simply print any object to show how is its internal state:

```
<?php

$router = new Phalcon\Mvc\Router();
print_r($router);
```

It's easy to know the internal state of any object. The above example prints the following:

```
Phalcon\Mvc\Router Object
(
    [_dependencyInjector:protected] =>
    [_module:protected] =>
    [_controller:protected] =>
    [_action:protected] =>
    [_params:protected] => Array
        (
            )
    [_routes:protected] => Array
        (
            [0] => Phalcon\Mvc\Router\Route Object
                (
                    [_pattern:protected] => #^/([a-zA-Z0-9\_]+) [/]{0,1}$
                    [_compiledPattern:protected] => #^/([a-zA-Z0-9\_]+) [/]{0,1}$
                    [_paths:protected] => Array
                        (
                            [controller] => 1
                        )

                    [_methods:protected] =>
                    [_id:protected] => 0
                    [_name:protected] =>
                )

            [1] => Phalcon\Mvc\Router\Route Object
                (
                    [_pattern:protected] => #^/([a-zA-Z0-9\_]+)/([a-zA-Z0-9\_]+)(/.*)*$#
                    [_compiledPattern:protected] => #^/([a-zA-Z0-9\_]+)/([a-zA-Z0-9\_]+)(/.*)*$#
                    [_paths:protected] => Array
                        (
                            [controller] => 1
                            [action] => 2
                            [params] => 3
                        )

                    [_methods:protected] =>
                    [_id:protected] => 1
                    [_name:protected] =>
                )

            )
    [_matchedRoute:protected] =>
    [_matches:protected] =>
    [_wasMatched:protected] =>
    [_defaultModule:protected] =>
    [_defaultController:protected] =>
    [_defaultAction:protected] =>
    [_defaultParams:protected] => Array
```

```
(  
)  
)
```

2.54.4 Using XDebug

XDebug is an amazing tool that complements the debugging of PHP applications. It is also a C extension for PHP, and you can use it together with Phalcon without additional configuration or side effects.

The following screencast shows a Xdebug session with Phalcon:

Once you have xdebug installed, you can use its API to get a more detailed information about exceptions and messages.

We highly recommend use at least XDebug 2.2.3 for a better compatibility with Phalcon

The following example implements `xdebug_print_function_stack` to stop the execution and generate a backtrace

```
<?php  
  
use Phalcon\Mvc\Controller;  
  
class SignupController extends Controller  
{  
  
    public function indexAction()  
    {  
  
    }  
  
    public function registerAction()  
    {  
  
        // Request variables from html form  
        $name = $this->request->getPost("name", "string");  
        $email = $this->request->getPost("email", "email");  
  
        // Stop execution and show a backtrace  
        return xdebug_print_function_stack("stop here!");  
  
        $user = new Users();  
        $user->name = $name;  
        $user->email = $email;  
  
        // Store and check for errors  
        $user->save();  
    }  
}
```

In this instance, Xdebug will also show us the variables in the local scope, and a backtrace as well:

```
Xdebug: stop here! in /Applications/MAMP/htdocs/tutorial/app/controllers/SignupController.php  
on line 19  
  
Call Stack:  
0.0383 654600 1. {main}() /Applications/MAMP/htdocs/tutorial/public/index.php:0  
0.0392 663864 2. Phalcon\Mvc\Application->handle()  
/Applications/MAMP/htdocs/tutorial/public/index.php:37  
0.0418 738848 3. SignupController->registerAction()  
/Applications/MAMP/htdocs/tutorial/public/index.php:0
```

```
0.0419    740144  4. xdebug_print_function_stack()
/Applications/MAMP/htdocs/tutorial/app/controllers/SignupController.php:19
```

Xdebug provides several ways to get debug and trace information regarding the execution of your application using Phalcon. You can check the [XDebug documentation](#) for more information.

2.55 Phalcon Developer Tools

These tools are a collection of useful scripts to generate skeleton code. Core components of your application can be generated with a simple command, allowing you to easily develop applications using Phalcon.

Important: Phalcon Framework version 0.5.0 or greater is needed to use developer tools. It is highly recommended to use PHP 5.4 or greater. If you prefer to use the web version instead of the console, this [blog post](#) offers more information.

2.55.1 Download

You can download or clone a cross platform package containing the developer tools from [Github](#).

Installation

These are detailed instructions on how to install the developer tools on different platforms:

Phalcon Developer Tools on Windows

These steps will guide you through the process of installing Phalcon Developer Tools for Windows.

Prerequisites The Phalcon PHP extension is required to run Phalcon Tools. If you haven't installed it yet, please see the [Installation](#) section for instructions.

Download You can download a cross platform package containing the developer tools from the [Download](#) section. Also you can clone it from [Github](#).

On the Windows platform, you need to configure the system PATH to include Phalcon tools as well as the PHP executable. If you download the Phalcon tools as a zip archive, extract it on any path of your local drive i.e. *c:\phalcon-tools*. You will need this path in the steps below. Edit the file "phalcon.bat" by right clicking on the file and selecting "Edit":

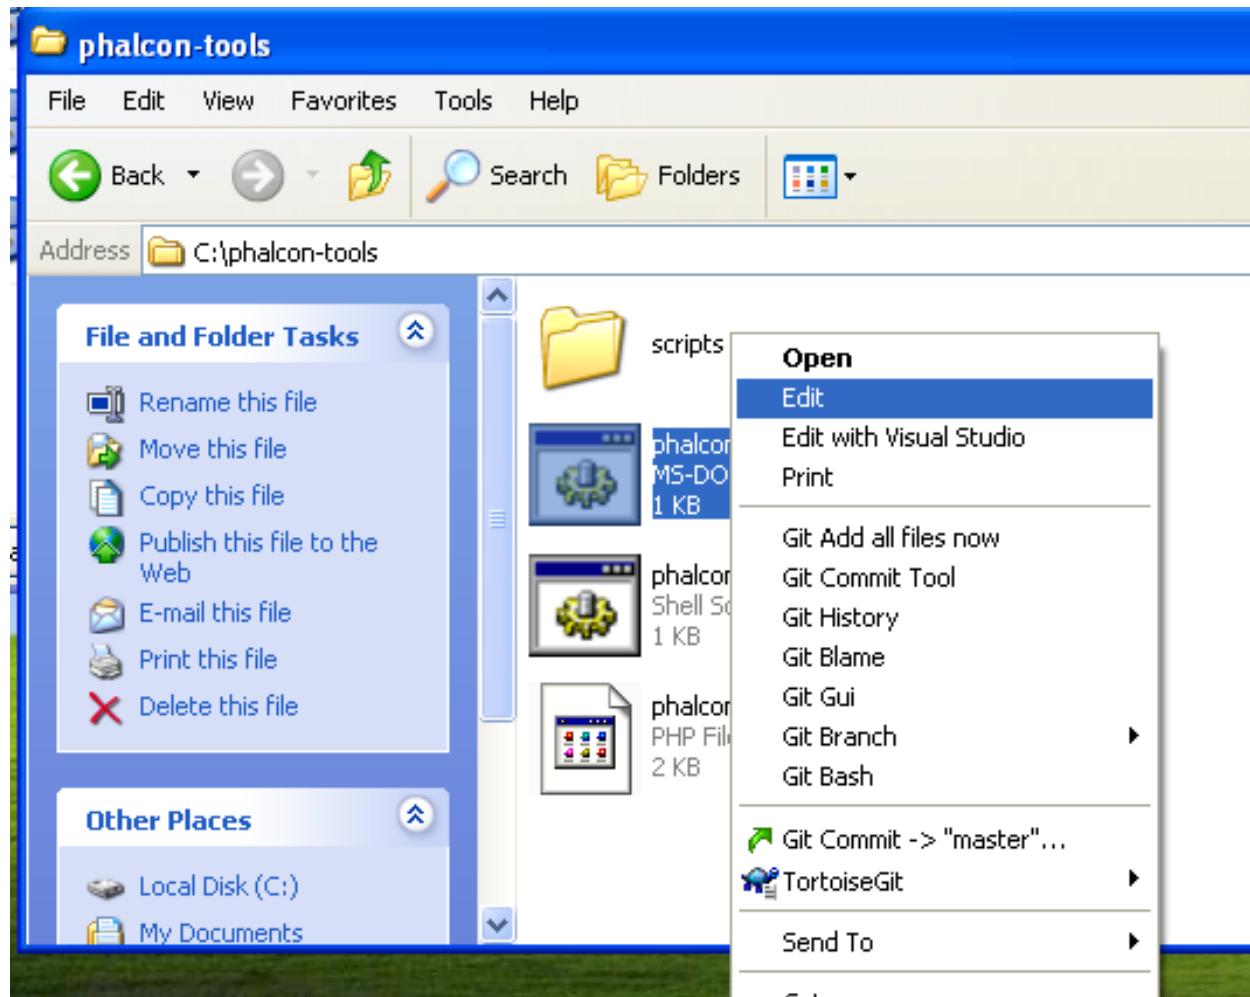

Change the path to the one you installed the Phalcon tools (set PTOOLSPATH=C:phalcon-tools):

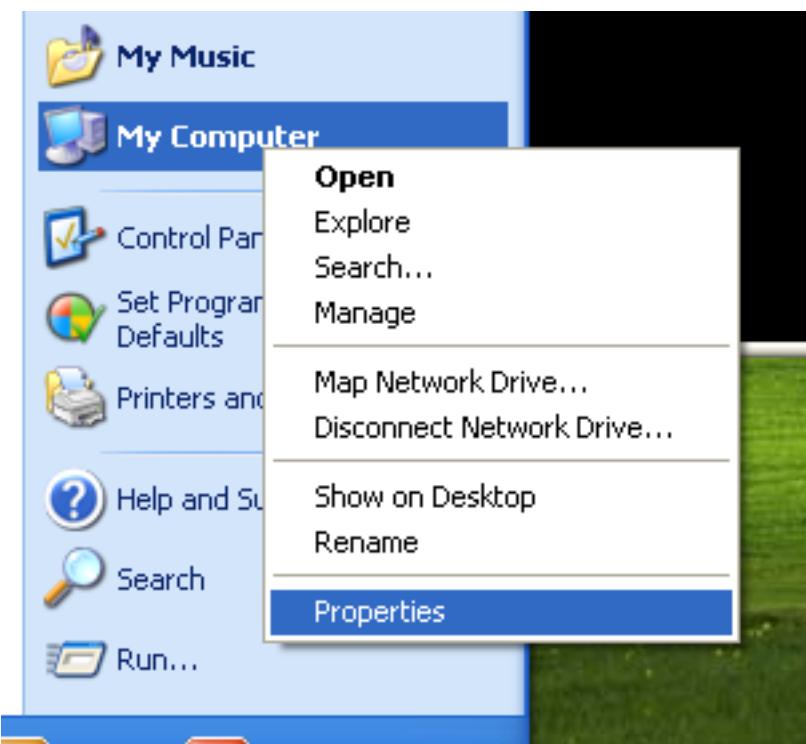

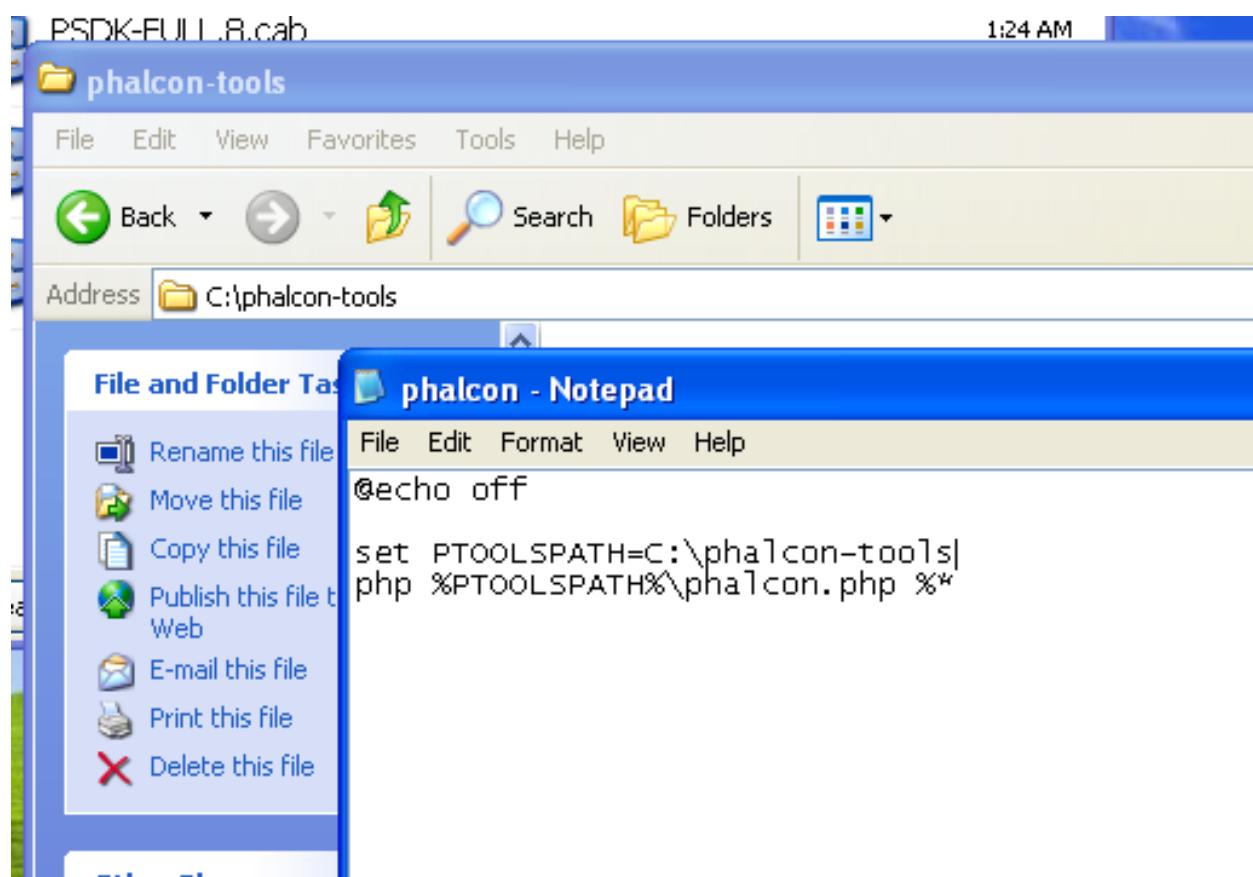

Save the changes.

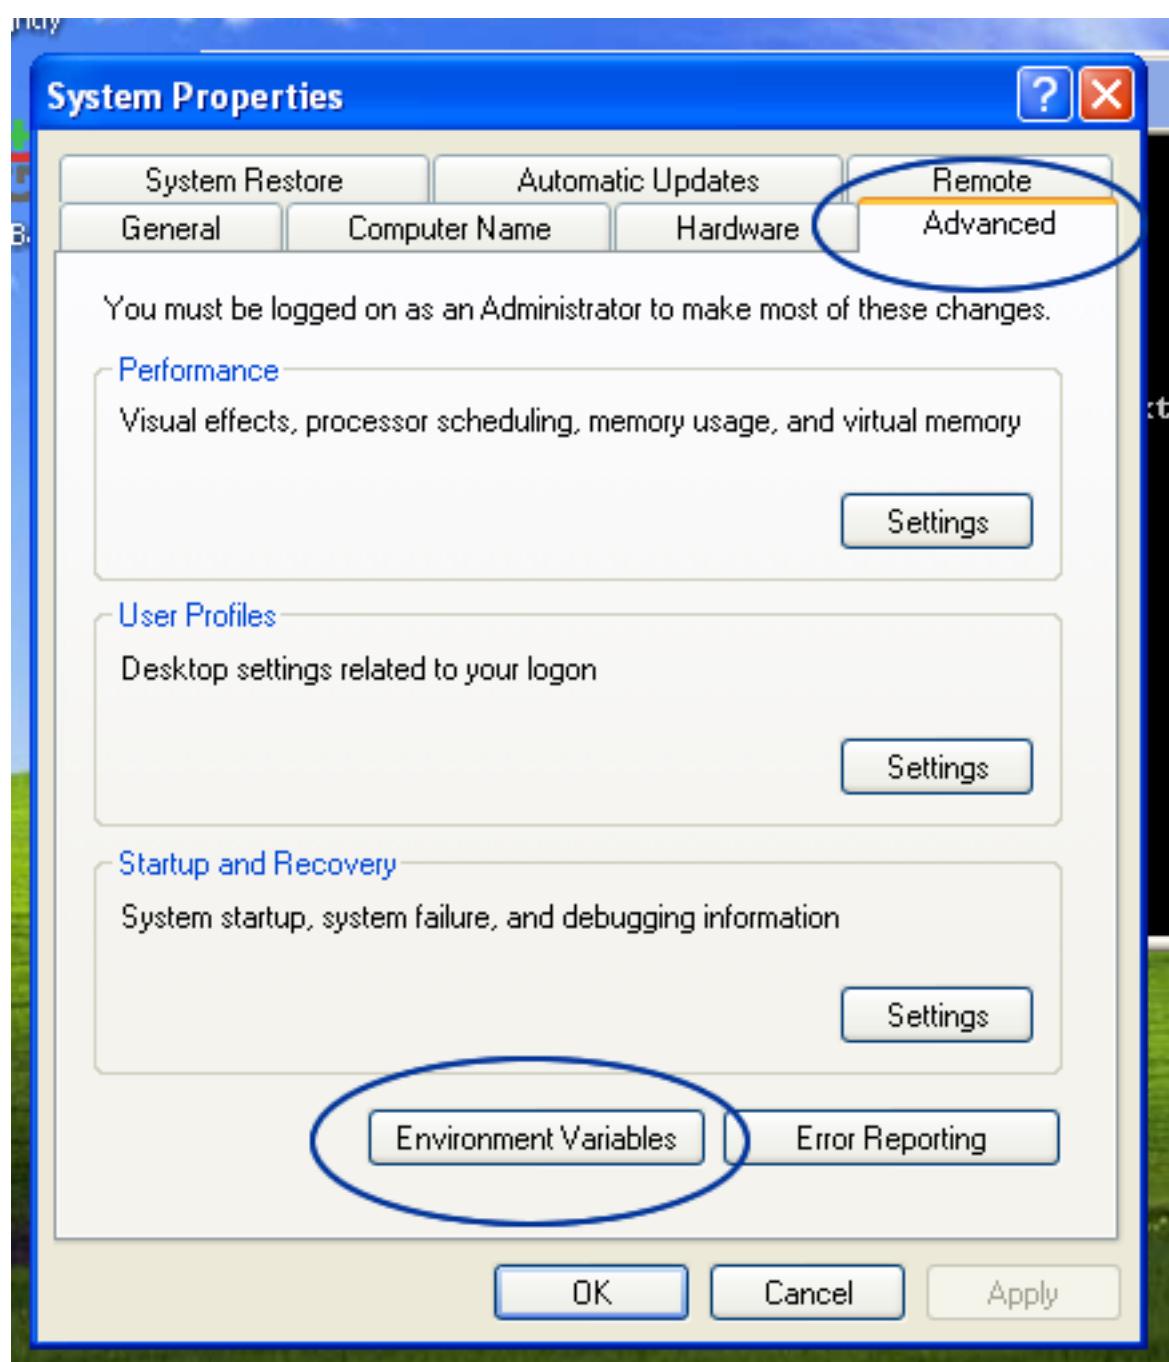

Adding PHP and Tools to your system PATH Because the scripts are written in PHP, you need to install it on your machine. Depending on your PHP installation, the executable can be located in various places. Search for the file php.exe and copy the path it is located in. For instance, if using the latest WAMP stack, PHP is located in: *C:\wampbin\php\php5.3.10\php.exe*.

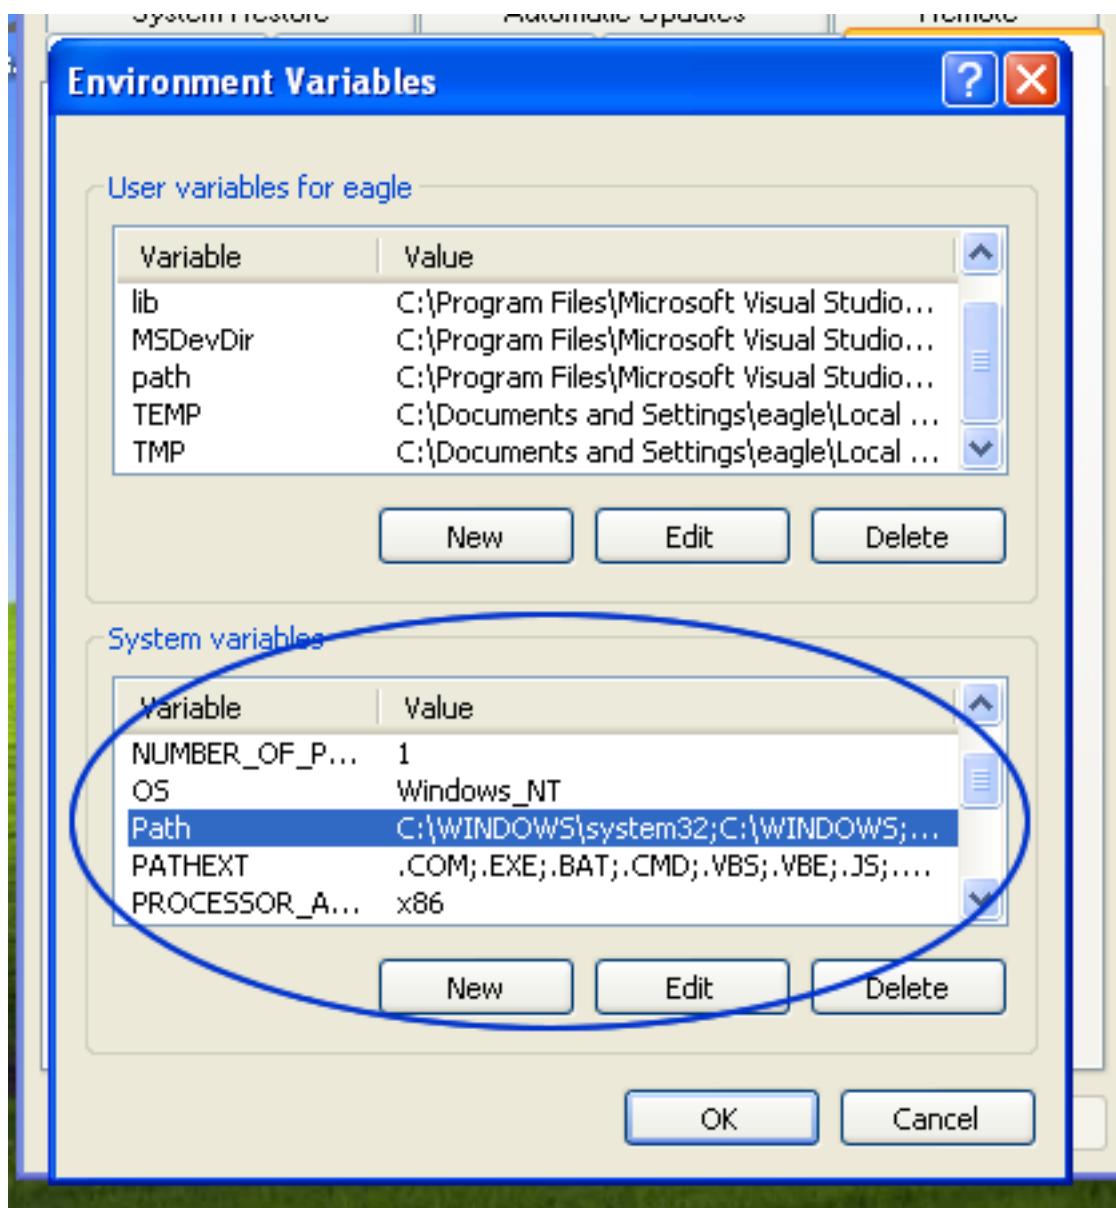

From the Windows start menu, right mouse click on the "My Computer" icon and select "Properties":

Click the "Advanced" tab and then the button "Environment Variables":

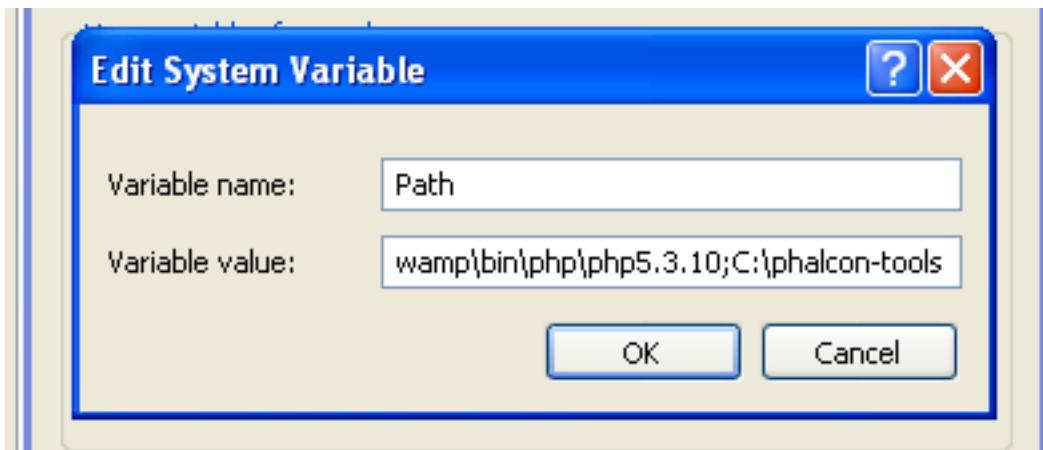

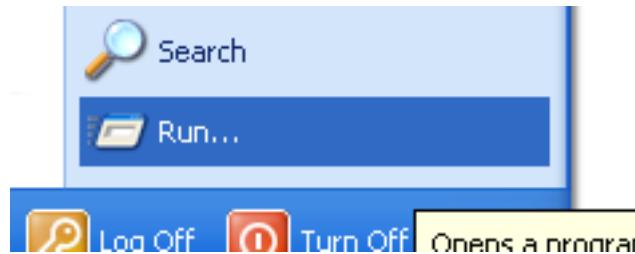

At the bottom, look for the section “System variables” and edit the variable “Path”:

Be very careful on this step! You need to append at the end of the long string the path where your php.exe was located and the path where Phalcon tools are installed. Use the “;” character to separate the different paths in the variable:

Accept the changes made by clicking “OK” and close the dialogs opened. From the start menu click on the option “Run”. If you can’t find this option, press “Windows Key” + “R”.

Type “cmd” and press enter to open the windows command line utility:

Type the commands “php -v” and “phalcon” and you will see something like this:

Congratulations you now have Phalcon tools installed!

Phalcon Developer Tools on Mac OS X

These steps will guide you through the process of installing Phalcon Developer Tools for OS/X.

Prerequisites The Phalcon PHP extension is required to run Phalcon Tools. If you haven’t installed it yet, please see the [Installation](#) section for instructions.

A screenshot of a Windows Command Prompt window titled "C:\WINDOWS\system32\cmd.exe". The window shows the following text:

```
C:\WINDOWS\system32\cmd.exe
Microsoft Windows XP [Version 5.1.2600]
(C) Copyright 1985-2001 Microsoft Corp.

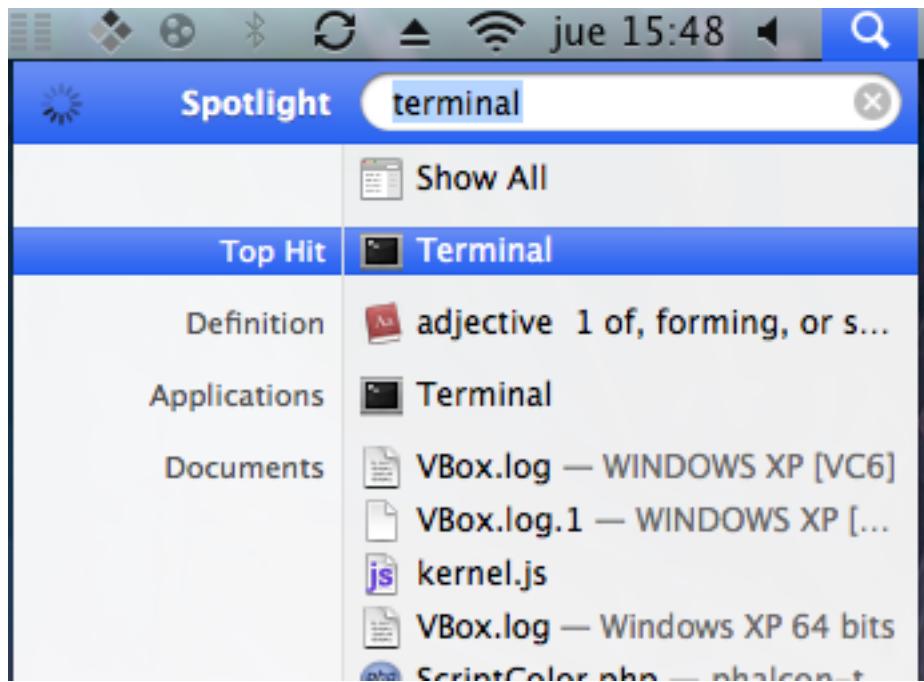

C:\Documents and Settings\eagle>php -v
PHP 5.3.10 (cli) (built: Feb 2 2012 20:27:51)
Copyright (c) 1997-2012 The PHP Group
Zend Engine v2.3.0, Copyright (c) 1998-2012 Zend Technologies
    with Xdebug v2.1.2, Copyright (c) 2002-2011, by Derick Rethans

C:\Documents and Settings\eagle>phalcon
Phalcon: incorrect usage

C:\Documents and Settings\eagle>
```

Download You can download a cross platform package containing the developer tools from the [Download](#) section. You can also clone it from [Github](#).

Open the terminal application:

Copy & Paste the commands below in your terminal:

```
wget -q --no-check-certificate -O phalcon-tools.zip http://github.com/phalcon/phalcon-devtools/zipball/master/phalcon-tools.zip
unzip -q phalcon-tools.zip
mv phalcon-phalcon-devtools-* phalcon-tools
```

Check where the phalcon-tools directory was installed using a `pwd` command in your terminal:

On the Mac platform, you need to configure your user PATH to include Phalcon tools. Edit your `.profile` and append the Phalcon tools path to the environment variable PATH:

Insert these two lines at the end of the file:

```
export PATH=$PATH:/Users/scott/phalcon-tools
export PTOOLSPATH=/Users/scott/phalcon-tools
```

The `.profile` should look like this:

Save your changes and close the editor. In the terminal window, type the following commands to create a symbolic link to the `phalcon.sh` script:

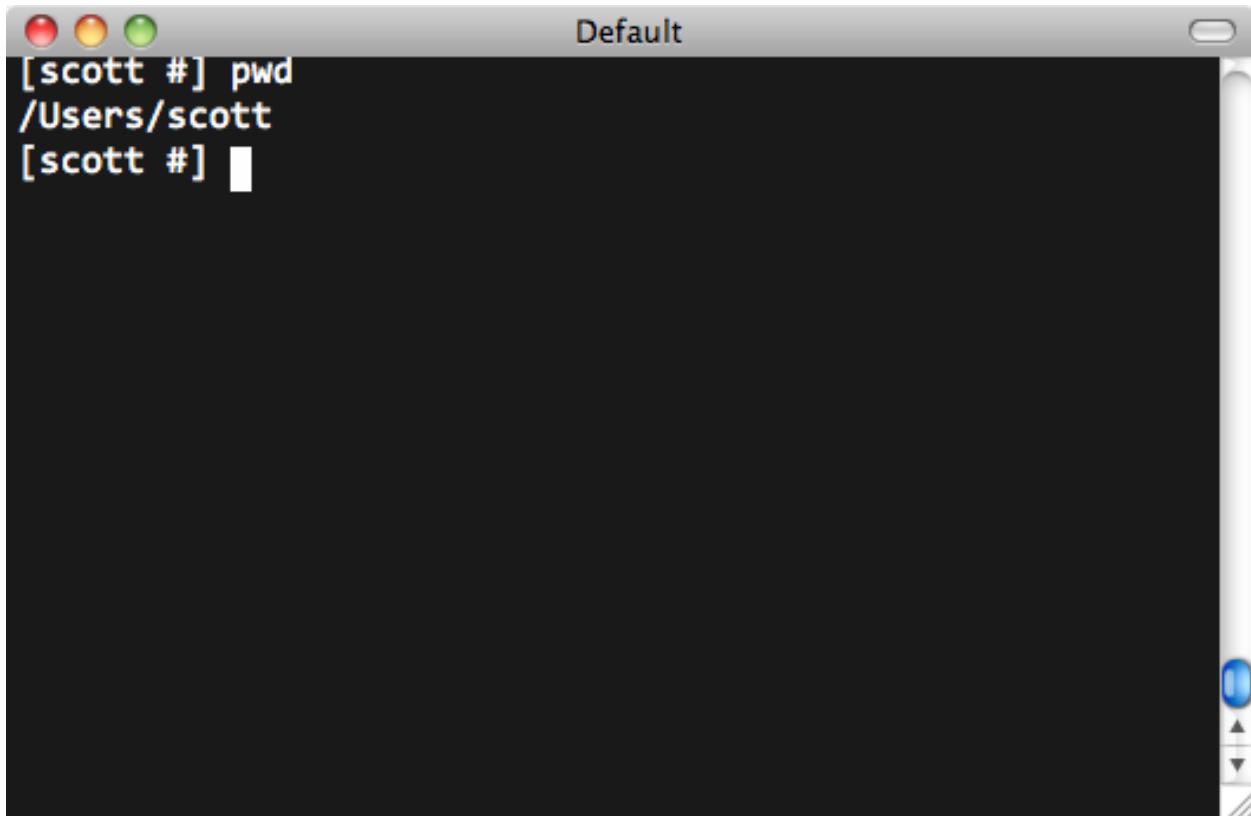

```
ln -s ~/phalcon-tools/phalcon.sh ~/phalcon-tools/phalcon
chmod +x ~/phalcon-tools/phalcon
```

Type the command “`phalcon`” and you will see something like this:

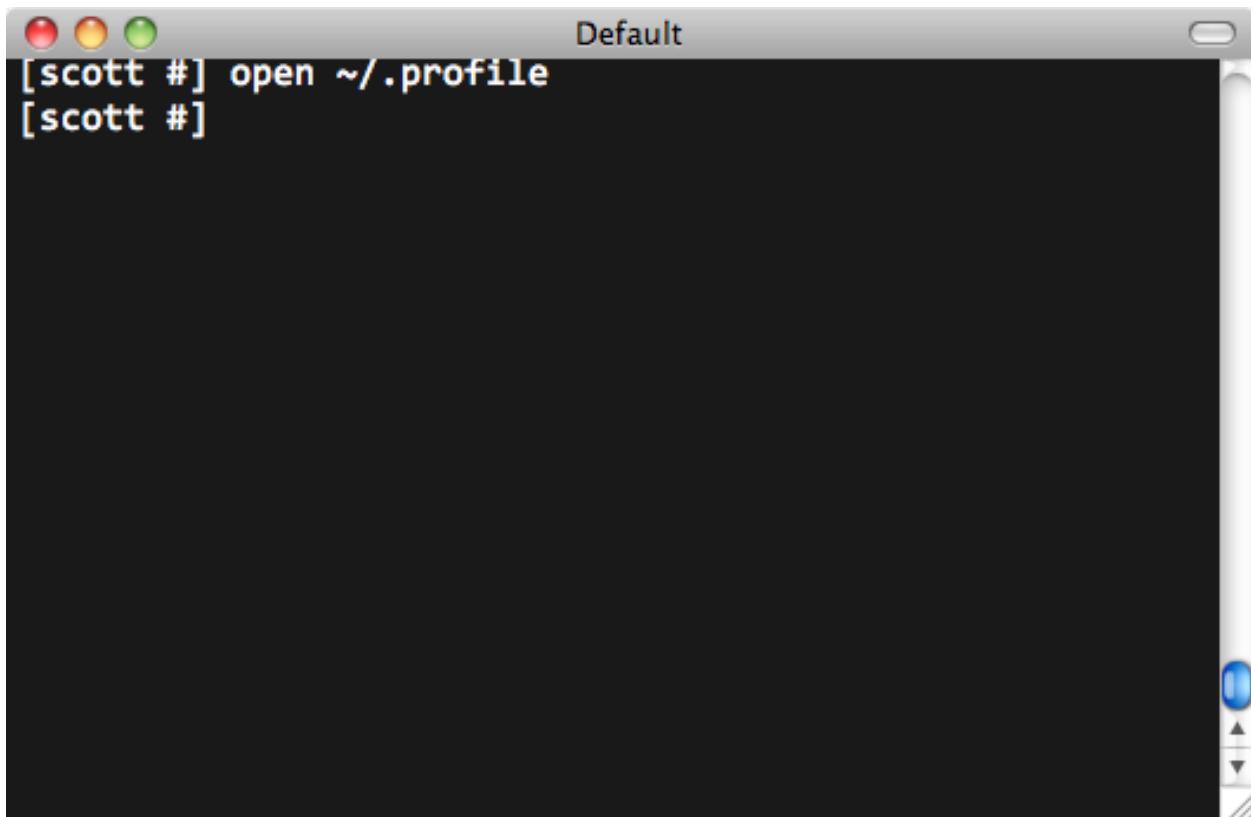

Congratulations you now have Phalcon tools installed!

Related Guides

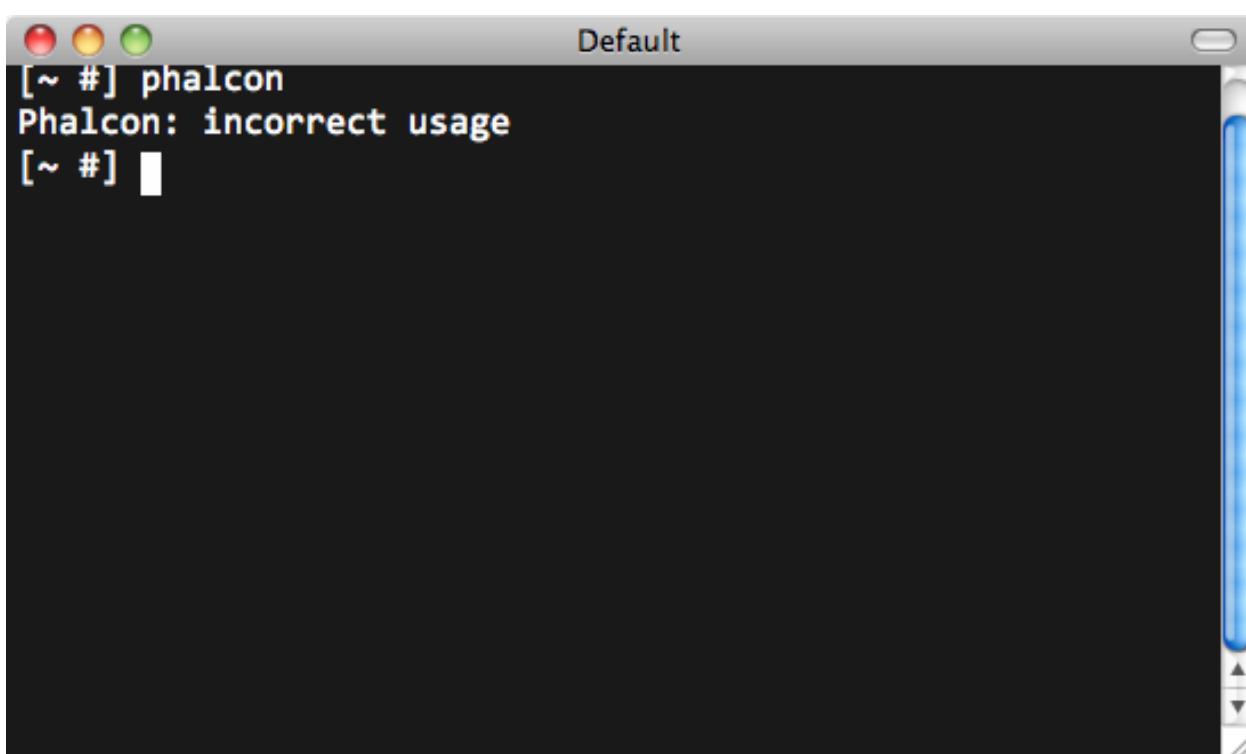

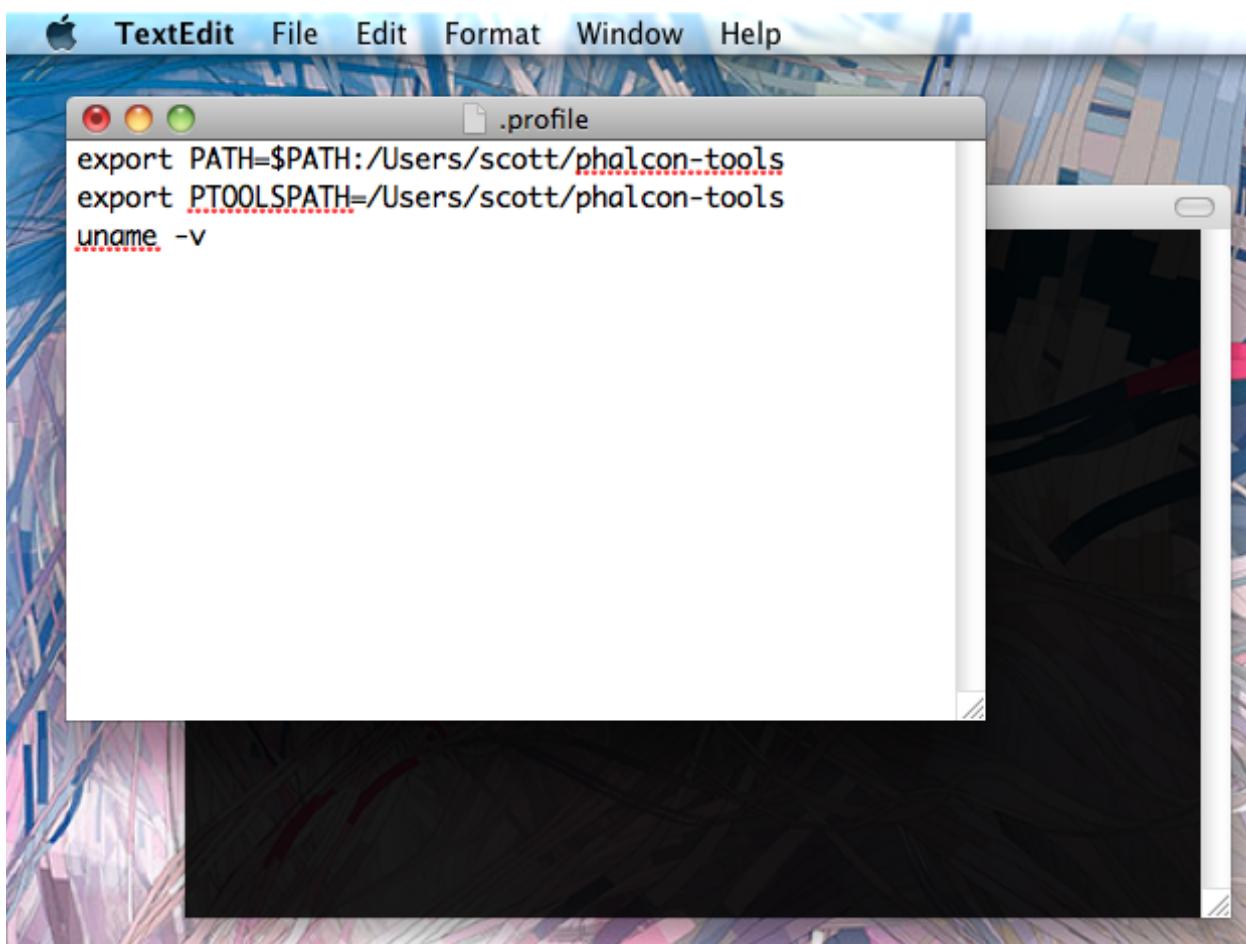

- [Using Developer Tools](#)

```
[scott #] pwd  
/Users/scott  
[scott #] [ ]
```

```
[scott #] open ~/.profile  
[scott #]
```

- Installation on Windows
- Installation on Linux

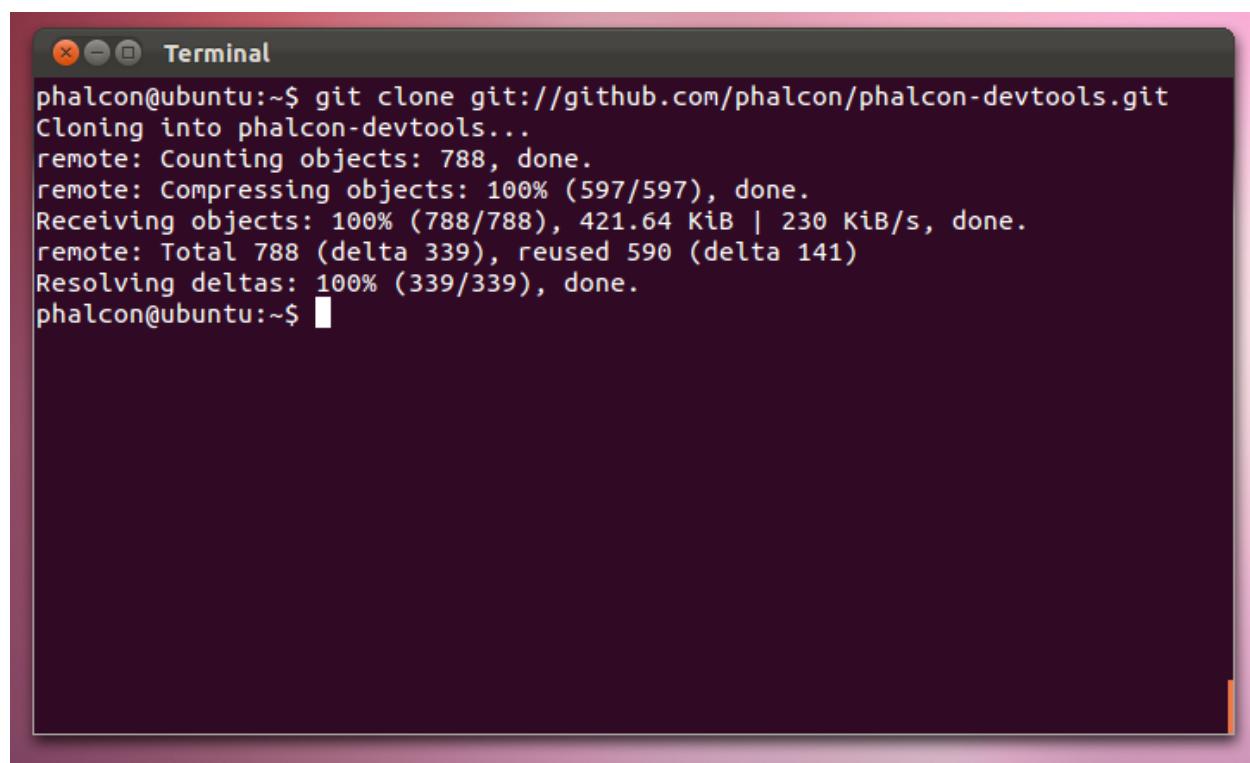

Phalcon Developer Tools on Linux

These steps will guide you through the process of installing Phalcon Developer Tools for Linux.

Prerequisites The Phalcon PHP extension is required to run Phalcon Tools. If you haven't installed it yet, please see the [Installation](#) section for instructions.

Download You can download a cross platform package containing the developer tools from the [Download](#) section. Also you can clone it from [Github](#).

Open a terminal and type the commands below:

```
Terminal
phalcon@ubuntu:~$ git clone git://github.com/phalcon/phalcon-devtools.git
Cloning into phalcon-devtools...
remote: Counting objects: 788, done.
remote: Compressing objects: 100% (597/597), done.
Receiving objects: 100% (788/788), 421.64 KiB | 230 KiB/s, done.
remote: Total 788 (delta 339), reused 590 (delta 141)
Resolving deltas: 100% (339/339), done.
phalcon@ubuntu:~$
```

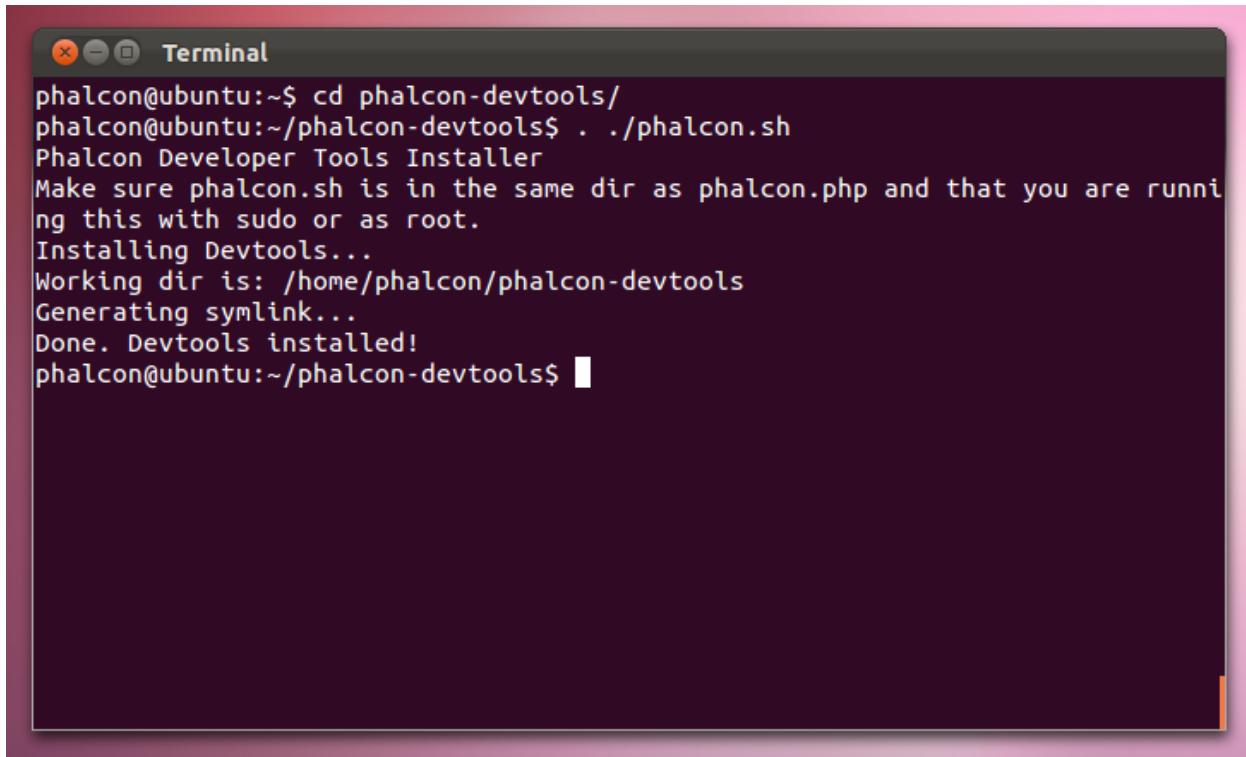

Then enter the folder where the tools were cloned and execute ". ./phalcon.sh", (don't forget the dot at beginning of the command):

Create a symbolink link to the phalcon.php script:

```
ln -s ~/phalcon-devtools/phalcon.php /usr/bin/phalcon
```

```
chmod ugo+x /usr/bin/phalcon
```

Congratulations you now have Phalcon tools installed!

A screenshot of a terminal window titled "Terminal". The window has a dark background and light-colored text. It shows the command "phalcon@ubuntu:~\$ cd phalcon-devtools/" followed by ". ./phalcon.sh". The output of the script is displayed, including messages about the Phalcon Developer Tools Installer, the working directory, generating symlinks, and confirming the installation is done. The terminal ends with "phalcon@ubuntu:~/phalcon-devtools\$ █".

Related Guides

- [Using Developer Tools](#)
- [Installation on Windows](#)
- [Installation on Mac](#)

2.55.2 Getting Available Commands

You can get a list of available commands in Phalcon tools by typing: phalcon commands

```
$ phalcon commands

Phalcon DevTools (1.2.3)

Available commands:
  commands (alias of: list, enumerate)
  controller (alias of: create-controller)
  model (alias of: create-model)
  all-models (alias of: create-all-models)
  project (alias of: create-project)
  scaffold
  migration
  webtools
```

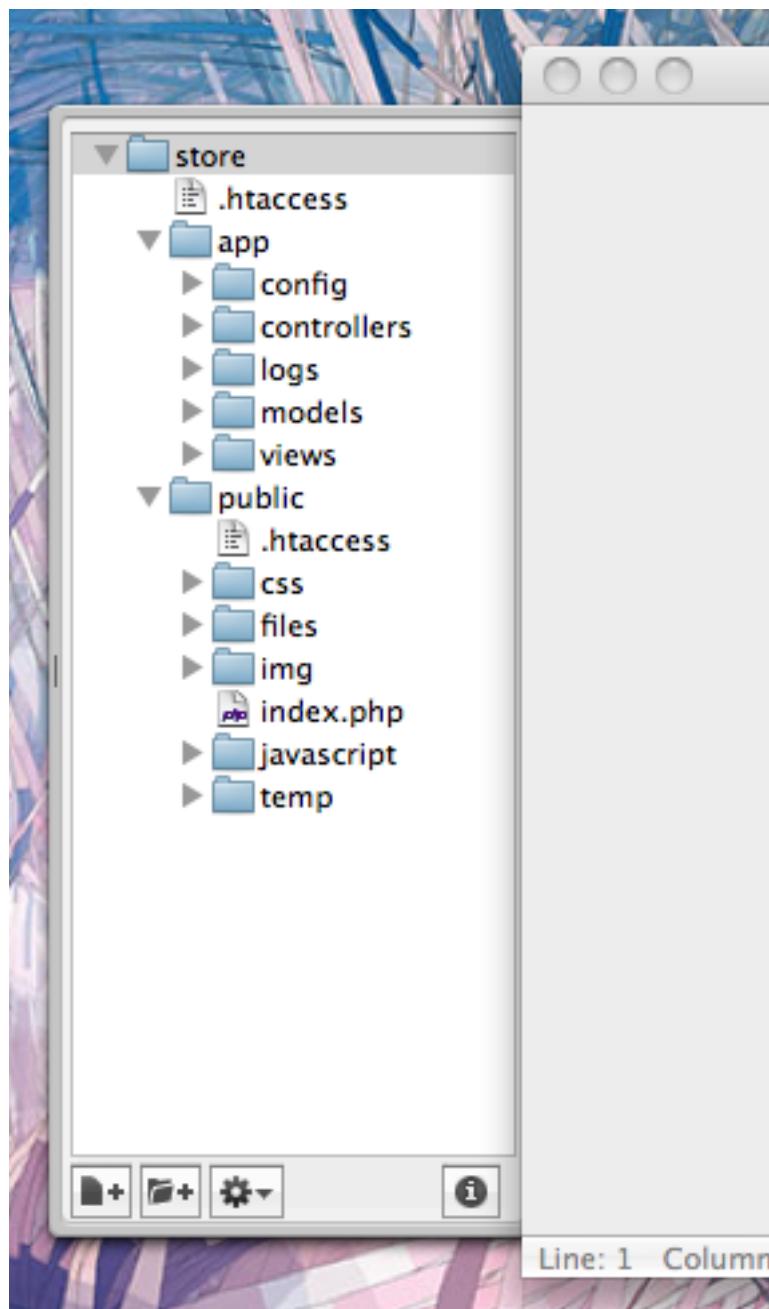

2.55.3 Generating a Project Skeleton

You can use Phalcon tools to generate pre-defined project skeletons for your applications with Phalcon framework. By default the project skeleton generator will use mod_rewrite for Apache. Type the following command on your web

server document root:

```
$ pwd  
/Applications/MAMP/htdocs  
$ phalcon create-project store
```

The above recommended project structure was generated:

You could add the parameter `-help` to get help on the usage of a certain script:

Phalcon DevTools (1.2.3)

Help: Creates a project

Usage: project [name] [type] [directory] [enable-webtools]

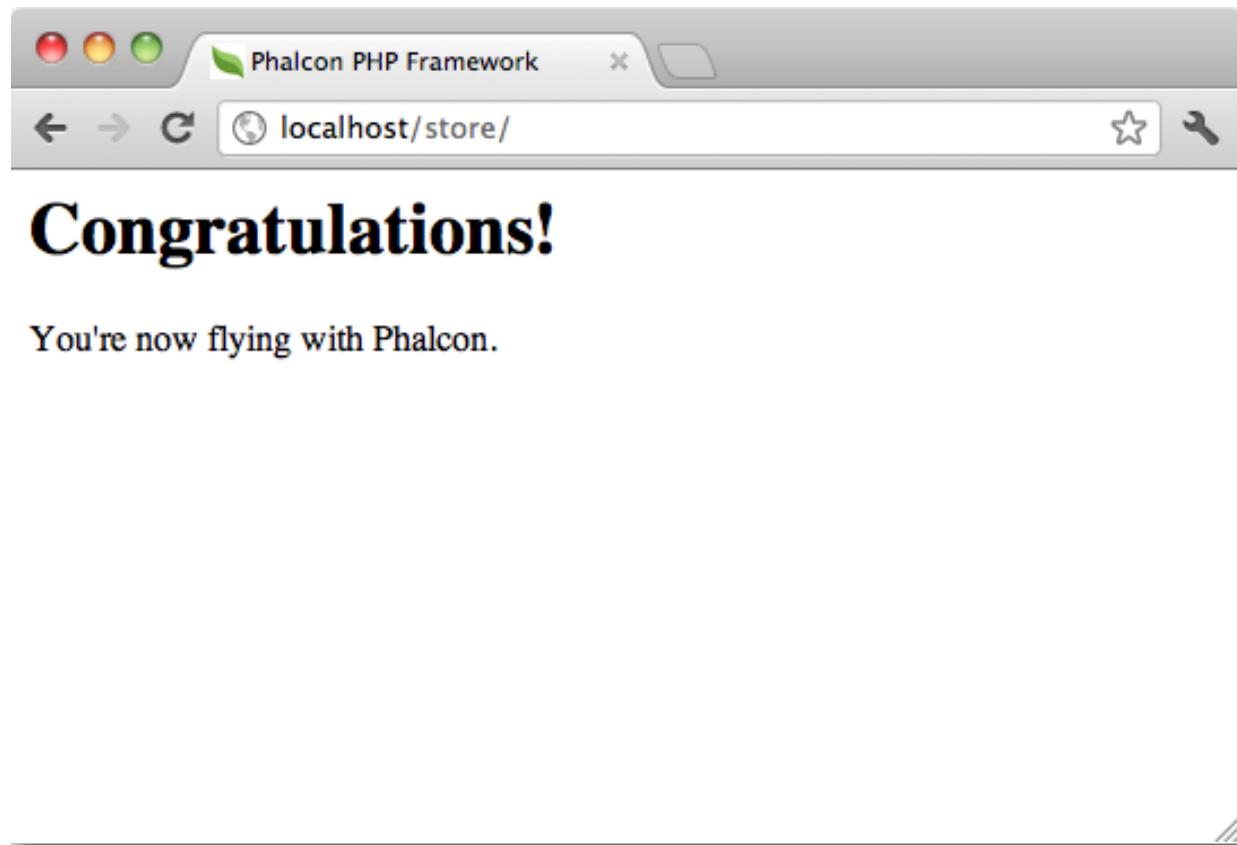

Arguments: help Shows this help text

Example phalcon project store simple

Options:

--name	Name of the new project
--enable-webtools	Determines if webtools should be enabled [optional]
--directory=s	Base path on which project will be created [optional]
--type=s	Type of the application to be generated (micro, simple, modules)
--template-path	Specify a template path [optional]
--use-config-ini	Use a ini file as configuration file [optional]
--trace	Shows the trace of the framework in case of exception. [optional]
--help	Shows this help

Accessing the project from the web server will show you:

2.55.4 Generating Controllers

The command “create-controller” generates controller skeleton structures. It’s important to invoke this command inside a directory that already has a Phalcon project.

```
$ phalcon create-controller --name test
```

The following code is generated by the script:

```
<?php

class TestController extends Phalcon\Mvc\Controller
{

    public function indexAction()
    {

    }

}
```

2.55.5 Preparing Database Settings

When a project is generated using developer tools. A configuration file can be found in *app/config/config.ini* To generate models or scaffold, you will need to change the settings used to connect to your database.

Change the database section in your config.ini file:

```
[database]
adapter = Mysql
host = "127.0.0.1"
username = "root"
password = "secret"
dbname = "store_db"

[phalcon]
controllersDir = "../app/controllers/"
modelsDir = "../app/models/"
viewsDir = "../app/views/"
baseUri = "/store/"
```

2.55.6 Generating Models

There are several ways to create models. You can create all models from the default database connection or some selectively. Models can have public attributes for the field representations or setters/getters can be used.

Options:

--name=s	Table name
--schema=s	Name of the schema. [optional]
--namespace=s	Model's namespace [optional]
--get-set	Attributes will be protected and have setters/getters. [optional]
--extends=s	Model extends the class name supplied [optional]
--doc	Helps to improve code completion on IDEs [optional]

--directory=	Base path on which project will be created [optional]
--force	Rewrite the model. [optional]
--trace	Shows the trace of the framework in case of exception. [optional]
--mapcolumn	Get some code for map columns. [optional]

The simplest way to generate a model is:

```
$ phalcon model products
```

```
$ phalcon model --name tablename
```

All table fields are declared public for direct access.

```
<?php

class Products extends \Phalcon\Mvc\Model
{

    /**
     * @var integer
     */
    public $id;

    /**
     * @var integer
     */
    public $types_id;

    /**
     * @var string
     */
    public $name;

    /**
     * @var string
     */
    public $price;

    /**
     * @var integer
     */
    public $quantity;

    /**
     * @var string
     */
    public $status;

}
```

By adding the *-get-set* you can generate the fields with protected variables and public setter/getter methods. Those methods can help in business logic implementation within the setter/getter methods.

```
<?php

class Products extends \Phalcon\Mvc\Model
{
```

```
/**
 * @var integer
 */
protected $id;

/**
 * @var integer
 */
protected $types_id;

/**
 * @var string
 */
protected $name;

/**
 * @var string
 */
protected $price;

/**
 * @var integer
 */
protected $quantity;

/**
 * @var string
 */
protected $status;

/**
 * Method to set the value of field id
 * @param integer $id
 */
public function setId($id)
{
    $this->id = $id;
}

/**
 * Method to set the value of field types_id
 * @param integer $types_id
 */
public function setTypesId($types_id)
{
    $this->types_id = $types_id;
}

...

/**
 * Returns the value of field status
 * @return string
 */
public function getStatus()
{
    return $this->status;
```

```

    }
}

```

A nice feature of the model generator is that it keeps changes made by the developer between code generations. This allows the addition or removal of fields and properties, without worrying about losing changes made to the model itself. The following screencast shows you how it works:

2.55.7 Scaffold a CRUD

Scaffolding is a quick way to generate some of the major pieces of an application. If you want to create the models, views, and controllers for a new resource in a single operation, scaffolding is the tool for the job.

Once the code is generated, it will have to be customized to meet your needs. Many developers avoid scaffolding entirely, opting to write all or most of their source code from scratch. The generated code can serve as a guide to better understand of how the framework works or develop prototypes. The screenshot below shows a scaffold based on the table “products”:

```
$ phalcon scaffold --table-name test
```

The scaffold generator will build several files in your application, along with some folders. Here’s a quick overview of what will be generated:

File	Purpose
app/controllers/ProductsController.php	The Products controller
app/models/Products.php	The Products model
app/views/layout/products.phtml	Controller layout for Products
app/views/products/new.phtml	View for the action “new”
app/views/products/edit.phtml	View for the action “edit”
app/views/products/search.phtml	View for the action “search”

When browsing the recently generated controller, you will see a search form and a link to create a new Product:

The “create page” allows you to create products applying validations on the Products model. Phalcon will automatically validate not null fields producing warnings if any of them is required.

After performing a search, a pager component is available to show paged results. Use the “Edit” or “Delete” links in front of each result to perform such actions.

2.55.8 Web Interface to Tools

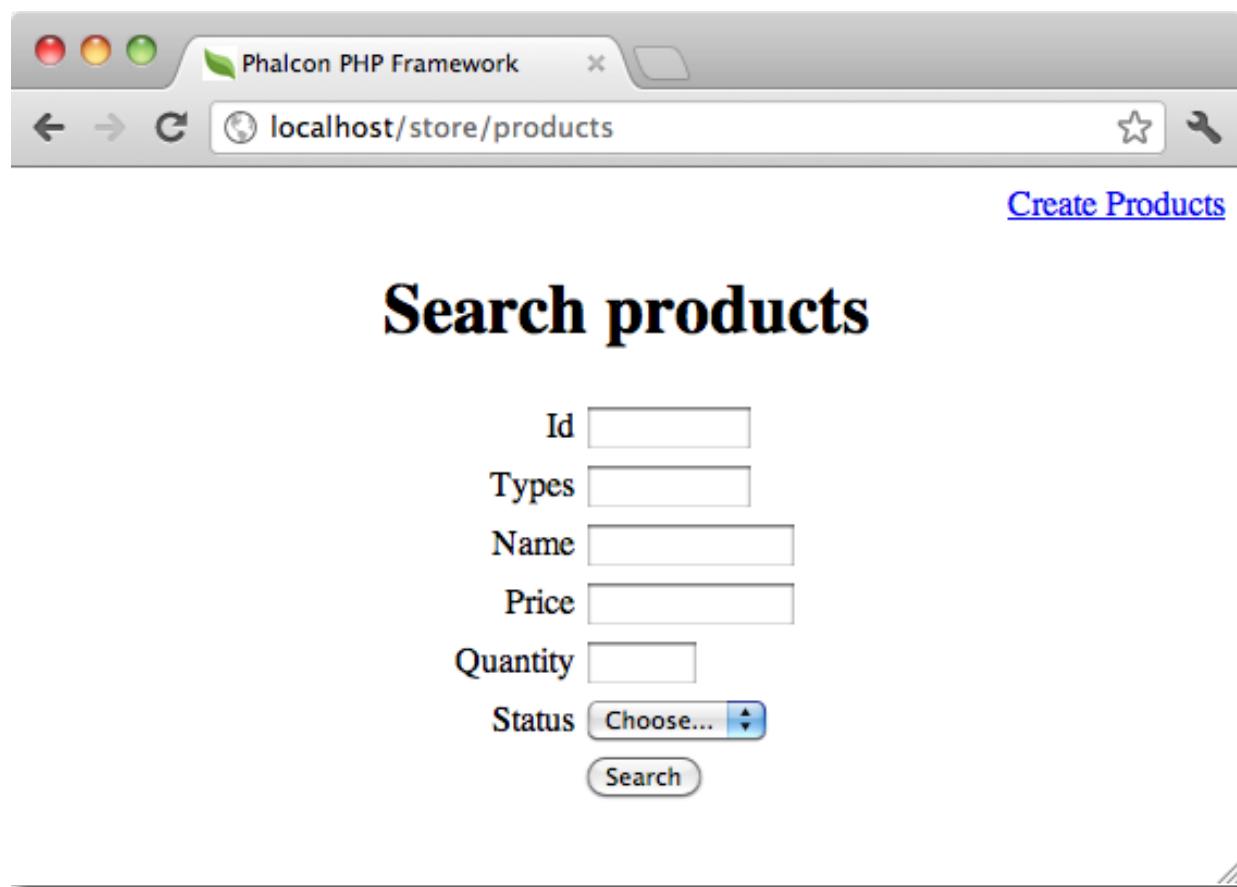

Also, if you prefer, it’s possible to use Phalcon Developer Tools from a web interface. Check out the following screencast to figure out how it works:

2.55.9 Integrating Tools with PhpStorm IDE

The screencast below shows how to integrate developer tools with the PhpStorm IDE. The configuration steps could be easily adapted to other IDEs for PHP.

2.55.10 Conclusion

Phalcon Developer Tools provides an easy way to generate code for your application, reducing development time and potential coding errors.

The screenshot shows a web browser window with the following details:

- Title Bar:** Phalcon PHP Framework
- Address Bar:** localhost/store/products/create/
- Buttons:** Go Back, Save (highlighted in blue)
- Text:** types is required
name is required
price is required
- Section Header:** Create products
- Form Fields:**
 - Types: Input field
 - Name: Input field
 - Price: Input field
 - Quantity: Input field
 - Status: Choose... dropdown

The screenshot shows a web browser window with the following details:

- Title Bar:** Phalcon PHP Framework
- Address Bar:** localhost/store/products/search/
- Content Area:**
 - Links:** Go Back, Create products
 - Table Headers:** Id, Types, Name, Price, Quantity, Status
 - Table Data:**

Id	Types	Name	Price	Quantity	Status
1	1	Cabbage	10.50	15	A
2	1	Spinach	7.20	38	A
3	1	Tomato	5.25	2	A
 - Pagination:** First, Previous, Next, Last, 1/1

2.56 Increasing Performance: What's next?

Get faster applications requires refine many aspects: server, client, network, database, web server, static sources, etc. In this chapter we highlight scenarios where you can improve performance and how detect what is really slow in your application.

2.56.1 Profile on the Server

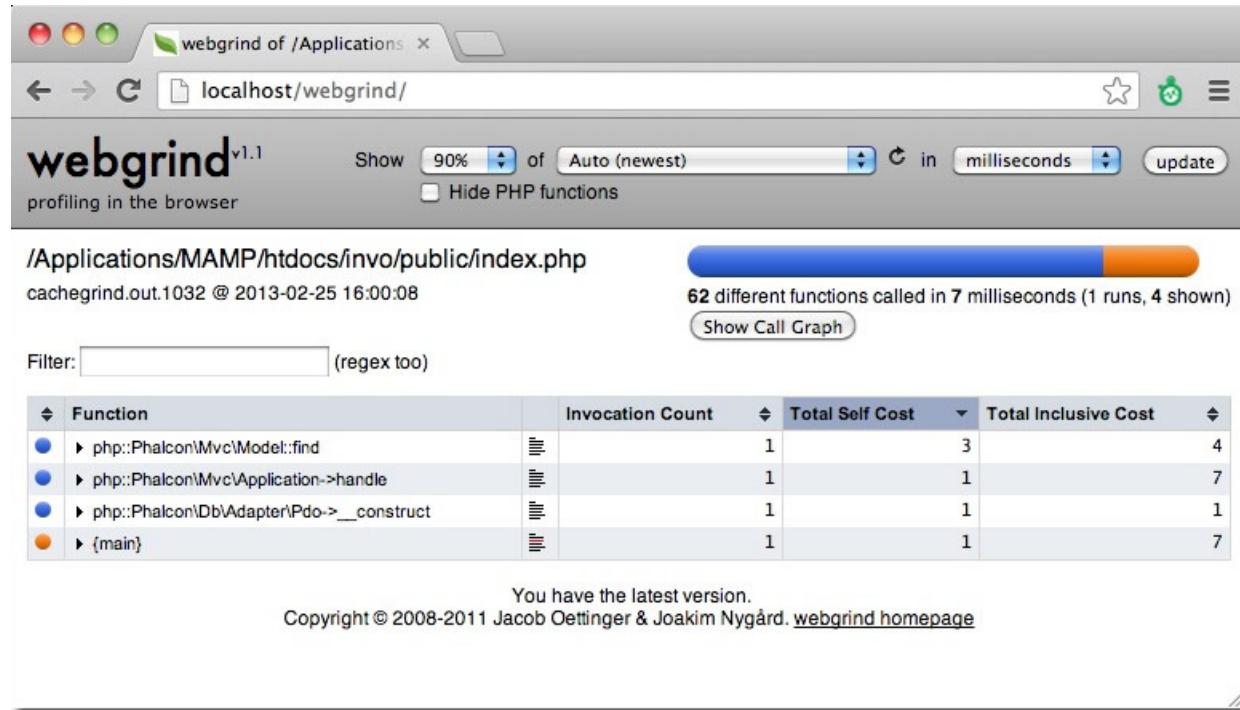

Each application is different, the permanent profiling is important to understand where performance can be increased. Profiling gives us a real picture on what is really slow and what does not. Profiles can vary between a request and another, so it is important to make enough measurements to make conclusions.

Profiling with XDebug

Xdebug provides an easier way to profile PHP applications, just install the extension and enable profiling in the php.ini:

```
xdebug.profiler_enable = On
```

Using a tool like [Webgrind](#) you can see which functions/methods are slower than others:

Profiling with Xhprof

[Xhprof](#) is another interesting extension to profile PHP applications. Add the following line to the start of the bootstrap file:

```
<?php  
  
xhprof_enable(XHPROF_FLAGS_CPU + XHPROF_FLAGS_MEMORY);
```

Then at the end of the file save the profiled data:

```
<?php

$xhprof_data = xhprof_disable('/tmp');

$XHPROF_ROOT = "/var/www/xhprof/";
include_once $XHPROF_ROOT . "/xhprof_lib/utils/xhprof_lib.php";
include_once $XHPROF_ROOT . "/xhprof_lib/utils/xhprof_runs.php";

$xhprof_runs = new XHProfRuns_Default();
$run_id = $xhprof_runs->save_run($xhprof_data, "xhprof_testing");

echo "http://localhost/xhprof/xhprof_html/index.php?run={$run_id}&source=xhprof_testing\n";
```

Xhprof provides a built-in html viewer to analize the profiled data:

Displaying top 100 functions: Sorted by Excl. Wall Time (microsec) [[display all](#)]

Function Name	Calls	Calls%	Incl. Wall Time (microsec)	IWall%	Excl. Wall Time (microsec)	EWall%	Incl. CPU (microsecs)	ICpu%	Excl. CPU (microsec)	ECPU%	Incl. MemUse (bytes)

Profiling SQL Statements

Most database systems provide tools to identify slow SQL statements. Detecting and fixing slow queries is very important in order to increase performance in the server side. In the Mysql case, you can use the slow query log to know what SQL queries are taking more time than expected:

```
log-slow-queries = /var/log/slow-queries.log
long_query_time = 1.5
```

2.56.2 Profile on the Client

Sometimes we may need to improve the loading of static elements such as images, javascript and css to improve performance. The following tools are useful to detect common bottlenecks in the client side:

Profile with Chrome/Firefox

Most modern browsers have tools to profile the page loading time. In Chrome you can use the web inspector to know how much time is taking the loading of the different resources required by a single page:

Firebug provides a similar functionality:

2.56.3 Yahoo! YSlow

YSlow analyzes web pages and suggests ways to improve their performance based on a set of rules for high performance web pages

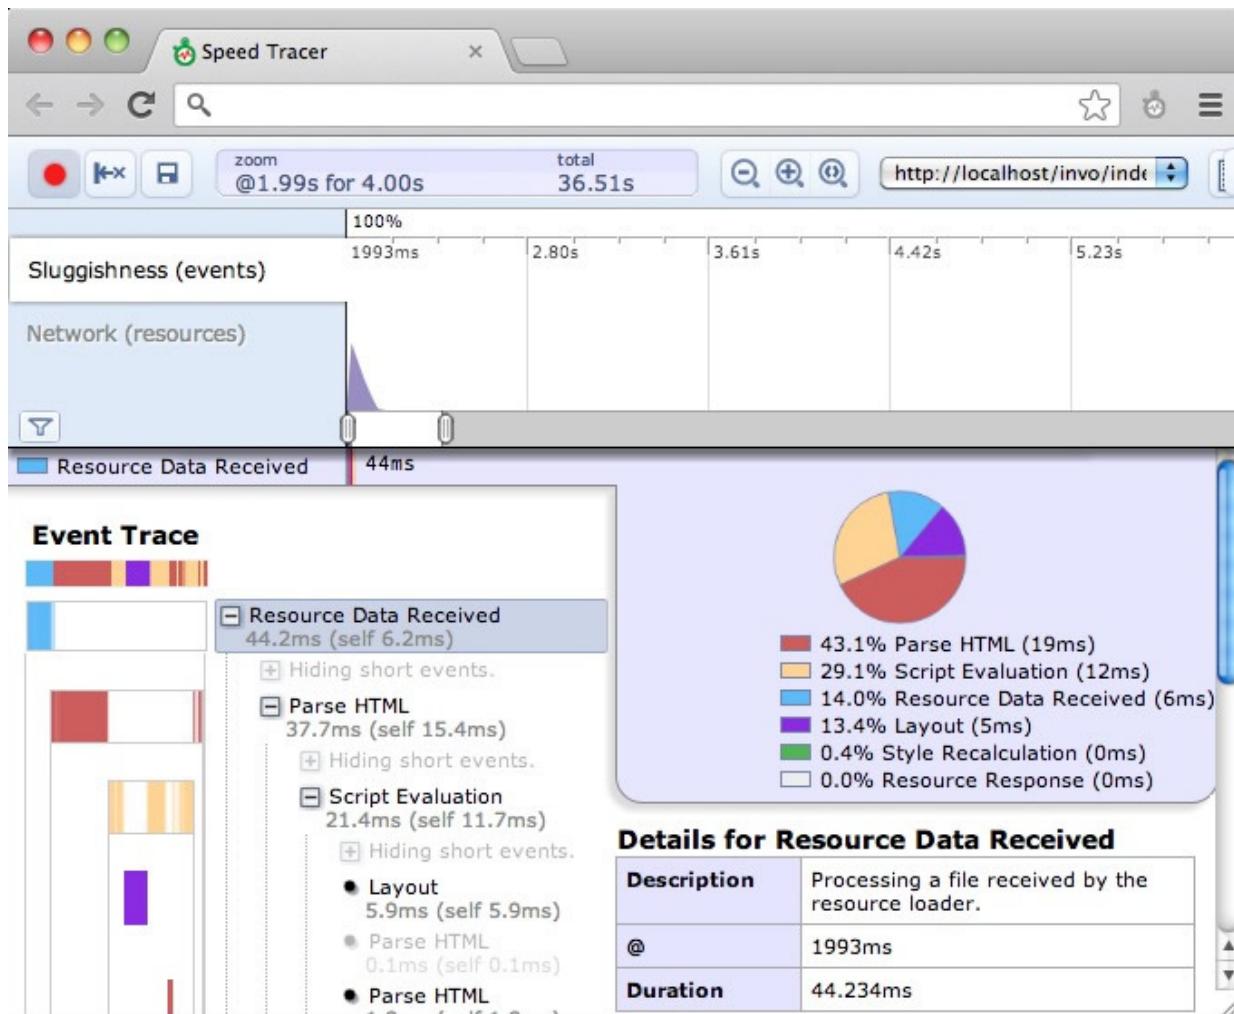

Profile with Speed Tracer

Speed Tracer is a tool to help you identify and fix performance problems in your web applications. It visualizes metrics that are taken from low level instrumentation points inside of the browser and analyzes them as your application runs. Speed Tracer is available as a Chrome extension and works on all platforms where extensions are currently supported (Windows and Linux).

This tool is very useful because it helps you to get the real time used to render the whole page including HTML parsing, Javascript evaluation and CSS styling.

2.56.4 Use a recent PHP version

PHP is faster every day, using the latest version improves the performance of your applications and also of Phalcon.

2.56.5 Use a PHP Bytecode Cache

APC as many other bytecode caches help an application to reduce the overhead of read, tokenize and parse PHP files in each request. Once the extension is installed use the following setting to enable APC:

```
apc.enabled = On
```

PHP 5.5 includes a built-in bytecode cache called ZendOptimizer+, this extension is also available for 5.3 and 5.4.

2.56.6 Do blocking work in the background

Process a video, send e-mails, compress a file or an image, etc., are slow tasks that must be processed in background jobs. There are a variety of tools that provide queuing or messaging systems that work well with PHP:

- Beanstalkd
- Redis
- RabbitMQ
- Resque
- Gearman
- ZeroMQ

2.56.7 Google Page Speed

mod_pagespeed speeds up your site and reduces page load time. This open-source Apache HTTP server module (also available for nginx as ngx_pagespeed) automatically applies web performance best practices to pages, and associated assets (CSS, JavaScript, images) without requiring that you modify your existing content or workflow.

2.57 Unit testing

Writing proper tests can assist in writing better software. If you set up proper test cases you can eliminate most functional bugs and better maintain your software.

2.57.1 Integrating PHPUnit with phalcon

If you don't already have phpunit installed, you can do it by using the following composer command:

```
composer require phpunit/phpunit
```

or by manually adding it to composer.json:

```
{  
    "require-dev": {  
        "phpunit/phpunit": "~4.5"  
    }  
}
```

Once phpunit is installed create a directory called 'tests' in your root directory:

```
app/
public/
tests/
```

Next, we need a ‘helper’ file to bootstrap the application for unit testing.

2.57.2 The **PHPunit** helper file

A helper file is required to bootstrap the application for running the tests. We have prepared a sample file. Put the file in your tests/ directory as TestHelper.php.

```
<?php
use Phalcon\DI,
    Phalcon\DI\FactoryDefault;

ini_set('display_errors',1);
error_reporting(E_ALL);

define('ROOT_PATH', __DIR__);
define('PATH_LIBRARY', __DIR__ . '/../app/library/');
define('PATH_SERVICES', __DIR__ . '/../app/services/');
define('PATH_RESOURCES', __DIR__ . '/../app/resources/');

set_include_path(
    ROOT_PATH . PATH_SEPARATOR . get_include_path()
);

// required for phalcon/incubator
include __DIR__ . "/../vendor/autoload.php";

// use the application autoloader to autoload the classes
// autoload the dependencies found in composer
$loader = new \Phalcon\Loader();

$loader->registerDirs(array(
    ROOT_PATH
));

$loader->register();

$di = new FactoryDefault();
DI::reset();

// add any needed services to the DI here

DI::setDefault($di);
```

Should you need to test any components from your own library, add them to the autoloader or use the autoloader from your main application.

To help you build the unit tests, we made a few abstract classes you can use to bootstrap the unit tests themselves. These files exist in the Phalcon incubator @ <https://github.com/phalcon/incubator>.

You can use the incubator library by adding it as a dependency:

```
composer require phalcon/incubator
```

or by manually adding it to composer.json:

```
{  
    "require": {  
        "phalcon/incubator": "dev-master"  
    }  
}
```

You can also clone the repository using the repo link above.

2.57.3 PHPUnit.xml file

Now, create a phpunit file:

```
<?xml version="1.0" encoding="UTF-8"?>  
<phpunit bootstrap=". /TestHelper.php"  
    backupGlobals="false"  
    backupStaticAttributes="false"  
    verbose="true"  
    colors="false"  
    convertErrorsToExceptions="true"  
    convertNoticesToExceptions="true"  
    convertWarningsToExceptions="true"  
    processIsolation="false"  
    stopOnFailure="false"  
    syntaxCheck="true">  
    <testsuite name="Phalcon - Testsuite">  
        <directory>. /</directory>  
    </testsuite>  
</phpunit>
```

Modify the phpunit.xml to fit your needs and save it in tests/.

This will run any tests under the tests/ directory.

2.57.4 Sample unit test

To run any unit tests you need to define them. The autoloader will make sure the proper files are loaded so all you need to do is create the files and phpunit will run the tests for you.

This example does not contain a config file, most test cases however, do need one. You can add it to the DI to get the UnitTestCase file.

First create a base unit test called UnitTestCase.php in your /tests directory:

```
<?php  
use Phalcon\DI,  
    \Phalcon\Test\UnitTestCase as PhalconTestCase;  
  
abstract class UnitTestCase extends PhalconTestCase {  
  
    /**  
     * @var \Voice\Cache  
     */  
    protected $_cache;  
  
    /**  
     * @var \Phalcon\Config  
     */
```

```

protected $_config;

< /**
 * @var bool
 */
private $_loaded = false;

public function setUp(Phalcon\DiInterface $di = NULL, Phalcon\Config $config = NULL) {

    // Load any additional services that might be required during testing
    $di = DI::getDefault();

    // get any DI components here. If you have a config, be sure to pass it to the parent
    parent::setUp($di);

    $this->_loaded = true;
}

< /**
 * Check if the test case is setup properly
 * @throws \PHPUnit_Framework_IncompleteTestError;
 */
public function __destruct() {
    if (!$this->_loaded) {
        throw new \PHPUnit_Framework_IncompleteTestError('Please run parent::setUp().');
    }
}
}

```

It's always a good idea to separate your Unit tests in namespaces. For this test we will create the namespace 'Test'. So create a file called tests/TestUnit.php:

```

<?php

namespace Test;

< /**
 * Class UnitTest
 */
class UnitTest extends \TestCase {

    public function testTestCase() {

        $this->assertEquals('works',
            'works',
            'This is OK'
        );

        $this->assertEquals('works',
            'works1',
            'This will fail'
        );
    }
}

```

Now when you execute 'phpunit' in your command-line from the tests directory you will get the following output:

```

$ phpunit
PHPUnit 3.7.23 by Sebastian Bergmann.

```

```
Configuration read from /private/var/www/tests/phpunit.xml

Time: 3 ms, Memory: 3.25Mb

There was 1 failure:

1) Test\PHPUnit::testTestCase
This will fail
Failed asserting that two strings are equal.
--- Expected
+++ Actual
@@ @@
-'works'
+'works1'

/private/var/www/tests/Test/UnitTest.php:25

FAILURES!
Tests: 1, Assertions: 2, Failures: 1.
```

Now you can start building your unit tests. You can view a good guide here (we also recommend reading the PHPUnit documentation if you're not familiar with PHPUnit):

<http://blog.stevensanderson.com/2009/08/24/writing-great-unit-tests-best-and-worst-practises/>

2.58 API Indice

2.58.1 Abstract class Phalcon\Acl

Constants

integer **ALLOW**

integer **DENY**

2.58.2 Class Phalcon\Acl\Adapter

Adapter for Phalcon\Acl adapters

Methods

public getActiveRole ()

Role which the list is checking if it's allowed to certain resource/access

public getActiveResource ()

Resource which the list is checking if some role can access it

public getActiveAccess ()

Active access which the list is checking if some role can access it

public setEventsManager (*unknown* \$eventsManager)

Sets the events manager

`public Phalcon\Events\ManagerInterface getEventsManager ()`

Returns the internal event manager

`public setDefaultAction (unknown $defaultAccess)`

Sets the default access level (Phalcon\Acl::ALLOW or Phalcon\Acl::DENY)

`public int getDefaultAction ()`

Returns the default ACL access level

2.58.3 Class Phalcon\Acl\Adapter\Memory

extends class Phalcon\Acl\Adapter

Manages ACL lists in memory

```
<?php

$acl = new \Phalcon\Acl\Adapter\Memory();

$acl->setDefaultAction(Phalcon\Acl::DENY);

//Register roles
$roles = array(
    'users' => new \Phalcon\Acl\Role('Users'),
    'guests' => new \Phalcon\Acl\Role('Guests')
);
foreach ($roles as $role) {
    $acl->addRole($role);
}

//Private area resources
$privateResources = array(
    'companies' => array('index', 'search', 'new', 'edit', 'save', 'create', 'delete'),
    'products' => array('index', 'search', 'new', 'edit', 'save', 'create', 'delete'),
    'invoices' => array('index', 'profile')
);
foreach ($privateResources as $resource => $actions) {
    $acl->addResource(new Phalcon\Acl\Resource($resource), $actions);
}

//Public area resources
$publicResources = array(
    'index' => array('index'),
    'about' => array('index'),
    'session' => array('index', 'register', 'start', 'end'),
    'contact' => array('index', 'send')
);
foreach ($publicResources as $resource => $actions) {
    $acl->addResource(new Phalcon\Acl\Resource($resource), $actions);
}

//Grant access to public areas to both users and guests
foreach ($roles as $role) {
    foreach ($publicResources as $resource => $actions) {
        $acl->allow($role->getName(), $resource, '*');
    }
}
```

```
//Grant access to private area to role Users
foreach ($privateResources as $resource => $actions) {
    foreach ($actions as $action) {
        $acl->allow('Users', $resource, $action);
    }
}
```

Methods

public __construct ()

Phalcon\Acl\Adapter\Memory constructor

public boolean addRole (unknown \$role, [unknown \$accessInherits])

Adds a role to the ACL list. Second parameter allows inheriting access data from other existing role Example:

```
<?php

$acl->addRole(new Phalcon\Acl\Role('administrator'), 'consultant');
$acl->addRole('administrator', 'consultant');
```

public addInherit (unknown \$roleName, unknown \$roleToInherit)

Do a role inherit from another existing role

public boolean isRole (unknown \$roleName)

Check whether role exist in the roles list

public boolean isResource (unknown \$resourceName)

Check whether resource exist in the resources list

public boolean addResource (unknown \$resourceValue, unknown \$accessList)

Adds a resource to the ACL list Access names can be a particular action, by example search, update, delete, etc or a list of them Example:

```
<?php

//Add a resource to the the list allowing access to an action
$acl->addResource(new Phalcon\Acl\Resource('customers'), 'search');
$acl->addResource('customers', 'search');

//Add a resource with an access list
$acl->addResource(new Phalcon\Acl\Resource('customers'), array('create', 'search'));
$acl->addResource('customers', array('create', 'search'));
```

public boolean addResourceAccess (unknown \$resourceName, unknown \$accessList)

Adds access to resources

public dropResourceAccess (unknown \$resourceName, unknown \$accessList)

Removes an access from a resource

protected _allowOrDeny (unknown \$roleName, unknown \$resourceName, unknown \$access, unknown \$action)

Checks if a role has access to a resource

public allow (unknown \$roleName, unknown \$resourceName, unknown \$access)

Allow access to a role on a resource You can use '*' as wildcard Example:

```
<?php

//Allow access to guests to search on customers
$acl->allow('guests', 'customers', 'search');

//Allow access to guests to search or create on customers
$acl->allow('guests', 'customers', array('search', 'create'));

//Allow access to any role to browse on products
$acl->allow('*', 'products', 'browse');

//Allow access to any role to browse on any resource
$acl->allow('*', '*', 'browse');
```

`public boolean deny (unknown $roleName, unknown $resourceName, unknown $access)`

Deny access to a role on a resource You can use '*' as wildcard Example:

```
<?php

//Deny access to guests to search on customers
$acl->deny('guests', 'customers', 'search');

//Deny access to guests to search or create on customers
$acl->deny('guests', 'customers', array('search', 'create'));

//Deny access to any role to browse on products
$acl->deny('*', 'products', 'browse');

//Deny access to any role to browse on any resource
$acl->deny('*', '*', 'browse');
```

`public boolean isAllowed (unknown $roleName, unknown $resourceName, unknown $access)`

Check whether a role is allowed to access an action from a resource

```
<?php

//Does andres have access to the customers resource to create?
$acl->isAllowed('andres', 'Products', 'create');

//Do guests have access to any resource to edit?
$acl->isAllowed('guests', '*', 'edit');
```

`public Phalcon\Acl\Role [] getRoles ()`

Return an array with every role registered in the list

`public Phalcon\Acl\Resource [] getResources ()`

Return an array with every resource registered in the list

`public getActiveRole ()` inherited from `Phalcon\Acl\Adapter`

Role which the list is checking if it's allowed to certain resource/access

`public getActiveResource ()` inherited from `Phalcon\Acl\Adapter`

Resource which the list is checking if some role can access it

`public getActiveAccess ()` inherited from `Phalcon\Acl\Adapter`

Active access which the list is checking if some role can access it

public **setEventsManager** (*unknown* \$eventsManager) inherited from Phalcon\Acl\Adapter

Sets the events manager

public **Phalcon\Events\ManagerInterface getEventsManager** () inherited from Phalcon\Acl\Adapter

Returns the internal event manager

public **setDefaultAction** (*unknown* \$defaultAccess) inherited from Phalcon\Acl\Adapter

Sets the default access level (Phalcon\Acl::ALLOW or Phalcon\Acl::DENY)

public **int getDefaultAction** () inherited from Phalcon\Acl\Adapter

Returns the default ACL access level

2.58.4 Class Phalcon\Acl\Exception

extends class Phalcon\Exception

Methods

final private *Exception __clone* () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string getMessage* () inherited from Exception

Gets the Exception message

final public *int getCode* () inherited from Exception

Gets the Exception code

final public *string getFile* () inherited from Exception

Gets the file in which the exception occurred

final public *int getLine* () inherited from Exception

Gets the line in which the exception occurred

final public *array getTrace* () inherited from Exception

Gets the stack trace

final public *Exception getPrevious* () inherited from Exception

Returns previous Exception

final public *Exception getTraceAsString* () inherited from Exception

Gets the stack trace as a string

public *string __toString* () inherited from Exception

String representation of the exception

2.58.5 Class Phalcon\Acl\Resource

This class defines resource entity and its description

Methods

```
public getName ()  
Resource name  
public __toString ()  
Resource name  
public getDescription ()  
Resource description  
public __construct (unknown $name, [unknown $description])  
Phalcon\Acl\Resource constructor
```

2.58.6 Class Phalcon\Acl\Role

This class defines role entity and its description

Methods

```
public getName ()  
Role name  
public __toString ()  
Role name  
public getDescription ()  
Role description  
public __construct (unknown $name, [unknown $description])  
Phalcon\Acl\Role constructor
```

2.58.7 Abstract class Phalcon\Annotations\Adapter

This is the base class for Phalcon\Annotations adapters

Methods

```
public setReader (unknown $reader)  
Sets the annotations parser  
public Phalcon\Annotations\ReaderInterface getReader ()  
Returns the annotation reader  
public Phalcon\Annotations\Reflection get (unknown $className)
```

Parses or retrieves all the annotations found in a class

`public array getMethods (unknown $className)`

Returns the annotations found in all the class' methods

`public Phalcon\Annotations\Collection getMethod (unknown $className, unknown $methodName)`

Returns the annotations found in a specific method

`public array getProperties (unknown $className)`

Returns the annotations found in all the class' methods

`public Phalcon\Annotations\Collection getProperty (unknown $className, unknown $propertyName)`

Returns the annotations found in a specific property

2.58.8 Class Phalcon\Annotations\Adapter\Apc

extends abstract class `Phalcon\Annotations\Adapter`

implements `Phalcon\Annotations\AdapterInterface`

Stores the parsed annotations in APC. This adapter is suitable for production

```
<?php  
$annotations = new \Phalcon\Annotations\Adapter\Apc();
```

Methods

`public __construct ([unknown $options])`

Phalcon\Annotations\Adapter\Apc constructor

`public Phalcon\Annotations\Reflection read (unknown $key)`

Reads parsed annotations from APC

`public write (unknown $key, unknown $data)`

Writes parsed annotations to APC

`public setReader (unknown $reader)` inherited from `Phalcon\Annotations\Adapter`

Sets the annotations parser

`public Phalcon\Annotations\ReaderInterface getReader ()` inherited from `Phalcon\Annotations\Adapter`

Returns the annotation reader

`public Phalcon\Annotations\Reflection get (unknown $className)` inherited from `Phalcon\Annotations\Adapter`

Parses or retrieves all the annotations found in a class

`public array getMethods (unknown $className)` inherited from `Phalcon\Annotations\Adapter`

Returns the annotations found in all the class' methods

`public Phalcon\Annotations\Collection getMethod (unknown $className, unknown $methodName)` inherited from `Phalcon\Annotations\Adapter`

Returns the annotations found in a specific method

`public array getProperties (unknown $className)` inherited from `Phalcon\Annotations\Adapter`

Returns the annotations found in all the class' methods

`public Phalcon\Annotations\Collection getProperty (unknown $className, unknown $propertyName)` inherited from `Phalcon\Annotations\Adapter`

Returns the annotations found in a specific property

2.58.9 Class Phalcon\Annotations\Adapter\Files

extends abstract class `Phalcon\Annotations\Adapter`

implements `Phalcon\Annotations\AdapterInterface`

Stores the parsed annotations in files. This adapter is suitable for production

```
<?php

$annotations = new \Phalcon\Annotations\Adapter\Files(array(
    'annotationsDir' => 'app/cache/annotations/'
));
```

Methods

`public __construct ([unknown $options])`

Phalcon\Annotations\Adapter\Files constructor

`public Phalcon\Annotations\Reflection read (unknown $key)`

Reads parsed annotations from files

`public write (unknown $key, unknown $data)`

Writes parsed annotations to files

`public setReader (unknown $reader)` inherited from `Phalcon\Annotations\Adapter`

Sets the annotations parser

`public Phalcon\Annotations\ReaderInterface getReader ()` inherited from `Phalcon\Annotations\Adapter`

Returns the annotation reader

`public Phalcon\Annotations\Reflection get (unknown $className)` inherited from `Phalcon\Annotations\Adapter`

Parses or retrieves all the annotations found in a class

`public array getMethods (unknown $className)` inherited from `Phalcon\Annotations\Adapter`

Returns the annotations found in all the class' methods

`public Phalcon\Annotations\Collection getMethod (unknown $className, unknown $methodName)` inherited from `Phalcon\Annotations\Adapter`

Returns the annotations found in a specific method

`public array getProperties (unknown $className)` inherited from `Phalcon\Annotations\Adapter`

Returns the annotations found in all the class' methods

`public Phalcon\Annotations\Collection getProperty (unknown $className, unknown $propertyName)` inherited from `Phalcon\Annotations\Adapter`

Returns the annotations found in a specific property

2.58.10 Class Phalcon\Annotations\Adapter\Memory

extends abstract class [Phalcon\Annotations\Adapter](#)

implements [Phalcon\Annotations\AdapterInterface](#)

- [Phalcon\Annotations\Adapter\Memory](#) * * Stores the parsed annotations in memory. This adapter is the suitable development/testing

Methods

public [Phalcon\Annotations\Reflection](#) **read** (*unknown* \$key)

Reads parsed annotations from memory

public **write** (*unknown* \$key, *unknown* \$data)

Writes parsed annotations to memory

public **setReader** (*unknown* \$reader) inherited from [Phalcon\Annotations\Adapter](#)

Sets the annotations parser

public [Phalcon\Annotations\ReaderInterface](#) **getReader** () inherited from [Phalcon\Annotations\Adapter](#)

Returns the annotation reader

public [Phalcon\Annotations\Reflection](#) **get** (*unknown* \$className) inherited from [Phalcon\Annotations\Adapter](#)

Parses or retrieves all the annotations found in a class

public *array* **getMethods** (*unknown* \$className) inherited from [Phalcon\Annotations\Adapter](#)

Returns the annotations found in all the class' methods

public [Phalcon\Annotations\Collection](#) **getMethod** (*unknown* \$className, *unknown* \$methodName) inherited from [Phalcon\Annotations\Adapter](#)

Returns the annotations found in a specific method

public *array* **getProperties** (*unknown* \$className) inherited from [Phalcon\Annotations\Adapter](#)

Returns the annotations found in all the class' methods

public [Phalcon\Annotations\Collection](#) **getProperty** (*unknown* \$className, *unknown* \$propertyName) inherited from [Phalcon\Annotations\Adapter](#)

Returns the annotations found in a specific property

2.58.11 Class Phalcon\Annotations\Adapter\Xcache

extends abstract class [Phalcon\Annotations\Adapter](#)

implements [Phalcon\Annotations\AdapterInterface](#)

Stores the parsed annotations to XCache. This adapter is suitable for production

```
<?php  
  
$annotations = new \Phalcon\Annotations\Adapter\Xcache();
```

Methods

public Phalcon\Annotations\Reflection `read` (*unknown \$key*)
 Reads parsed annotations from XCache

public `write` (*unknown \$key, Phalcon\Annotations\Reflection \$data*)
 Writes parsed annotations to XCache

public `setReader` (*unknown \$reader*) inherited from Phalcon\Annotations\Adapter
 Sets the annotations parser

public Phalcon\Annotations\ReaderInterface `getReader` () inherited from Phalcon\Annotations\Adapter
 Returns the annotation reader

public Phalcon\Annotations\Reflection `get` (*unknown \$className*) inherited from Phalcon\Annotations\Adapter
 Parses or retrieves all the annotations found in a class

public array `getMethods` (*unknown \$className*) inherited from Phalcon\Annotations\Adapter
 Returns the annotations found in all the class' methods

public Phalcon\Annotations\Collection `getMethod` (*unknown \$className, unknown \$methodName*) inherited from Phalcon\Annotations\Adapter
 Returns the annotations found in a specific method

public array `getProperties` (*unknown \$className*) inherited from Phalcon\Annotations\Adapter
 Returns the annotations found in all the class' methods

public Phalcon\Annotations\Collection `getProperty` (*unknown \$className, unknown \$propertyName*) inherited from Phalcon\Annotations\Adapter
 Returns the annotations found in a specific property

2.58.12 Class Phalcon\Annotations\Annotation

- **Phalcon\Annotations\Annotation** * * Represents a single annotation in an annotations collection

Methods

public __construct (*unknown \$reflectionData*)
 Phalcon\Annotations\Annotation constructor

public string `getName` ()
 Returns the annotation's name

public mixed `getExpression` (*unknown \$expr*)
 Resolves an annotation expression

public array `getExprArguments` ()
 Returns the expression arguments without resolving

public array `getArguments` ()
 Returns the expression arguments

public *int* **numberArguments** ()

Returns the number of arguments that the annotation has

public *mixed* **getArgument** (*unknown* \$position)

Returns an argument in a specific position

public *boolean* **hasArgument** (*unknown* \$position)

Returns an argument in a specific position

public *mixed* **getNamedArgument** (*unknown* \$name)

Returns a named argument

public *mixed* **getNamedParameter** (*unknown* \$name)

Returns a named parameter

2.58.13 Class Phalcon\Annotations\Collection

implements Iterator, Traversable, Countable

Represents a collection of annotations. This class allows to traverse a group of annotations easily

```
<?php

//Traverse annotations
foreach ($classAnnotations as $annotation) {
    echo 'Name=' , $annotation->getName() , PHP_EOL;
}

//Check if the annotations has a specific
var_dump($classAnnotations->has('Cacheable'));

//Get an specific annotation in the collection
$annotation = $classAnnotations->get('Cacheable');
```

Methods

public __construct ([*unknown* \$reflectionData])

Phalcon\Annotations\Collection constructor

public *int* **count** ()

Returns the number of annotations in the collection

public **rewind** ()

Rewinds the internal iterator

public Phalcon\Annotations\Annotation **current** ()

Returns the current annotation in the iterator

public *int* **key** ()

Returns the current position/key in the iterator

public **next** ()

Moves the internal iteration pointer to the next position

```
public boolean valid ()  
Check if the current annotation in the iterator is valid  
public Phalcon\Annotations\Annotation [] getAnnotations ()  
Returns the internal annotations as an array  
public Phalcon\Annotations\Annotation get (unknown $name)  
Returns the first annotation that match a name  
public Phalcon\Annotations\Annotation [] getAll (unknown $name)  
Returns all the annotations that match a name  
public boolean has (unknown $name)  
Check if an annotation exists in a collection
```

2.58.14 Class Phalcon\Annotations\Exception

extends Exception

Methods

```
final private Exception __clone () inherited from Exception  
Clone the exception  
public __construct ([string $message], [int $code], [Exception $previous]) inherited from Exception  
Exception constructor  
final public string getMessage () inherited from Exception  
Gets the Exception message  
final public int getCode () inherited from Exception  
Gets the Exception code  
final public string getFile () inherited from Exception  
Gets the file in which the exception occurred  
final public int getLine () inherited from Exception  
Gets the line in which the exception occurred  
final public array getTrace () inherited from Exception  
Gets the stack trace  
final public Exception getPrevious () inherited from Exception  
Returns previous Exception  
final public Exception getTraceAsString () inherited from Exception  
Gets the stack trace as a string  
public string __toString () inherited from Exception  
String representation of the exception
```

2.58.15 Class Phalcon\Annotations\Reader

implements `Phalcon\Annotations\ReaderInterface`

Parses docblocks returning an array with the found annotations

Methods

`public array parse (unknown $className)`

Reads annotations from the class dockblocks, its methods and/or properties

`public static array parseDocBlock (unknown $docBlock, [unknown $file], [unknown $line])`

Parses a raw doc block returning the annotations found

2.58.16 Class Phalcon\Annotations\Reflection

Allows to manipulate the annotations reflection in an OO manner

```
<?php

//Parse the annotations in a class
$reader = new \Phalcon\Annotations\Reader();
$parsing = reader->parse('MyComponent');

//Create the reflection
$reflection = new \Phalcon\Annotations\Reflection($parsing);

//Get the annotations in the class docblock
$classAnnotations = reflection->getClassAnnotations();
```

Methods

`public __construct ([unknown $reflectionData])`

Phalcon\Annotations\Reflection constructor

`public Phalcon\Annotations\Collection |false getClassAnnotations ()`

Returns the annotations found in the class docblock

`public Phalcon\Annotations\Collection [] getMethodsAnnotations ()`

Returns the annotations found in the methods' docblocks

`public Phalcon\Annotations\Collection [] getPropertiesAnnotations ()`

Returns the annotations found in the properties' docblocks

`public array getReflectionData ()`

Returns the raw parsing intermediate definitions used to construct the reflection

`public static array data __set_state (unknown $data)`

Restores the state of a Phalcon\Annotations\Reflection variable export

2.58.17 Class Phalcon\Assets\Collection

implements Countable, Iterator, Traversable

Methods

public **getPrefix** ()

...

public **getLocal** ()

...

public **getResources** ()

...

public **getCodes** ()

...

public **getPosition** ()

...

public **getFilters** ()

...

public **getAttributes** ()

...

public **getJoin** ()

...

public **getTargetUri** ()

...

public **getTargetPath** ()

...

public **getTargetLocal** ()

...

public **getSourcePath** ()

...

public **Phalcon\Assets\Collection add** (*unknown* \$resource)

Adds a resource to the collection

public **Phalcon\Assets\Collection addInline** (*unknown* \$code)

Adds a inline code to the collection

public **Phalcon\Assets\Collection addCss** (*unknown* \$path, [*unknown* \$local], [*unknown* \$filter], [*unknown* \$attributes])

Adds a CSS resource to the collection

public **Phalcon\Assets\Collection addInlineCss** (*unknown* \$content, [*unknown* \$filter], [*unknown* \$attributes])

Adds a inline CSS to the collection

public **Phalcon\Assets\Collection addJs** (*unknown* \$path, [*unknown* \$local], [*unknown* \$filter], [*unknown* \$attributes])

Adds a javascript resource to the collection

public **Phalcon\Assets\Collection addInlineJs** (*unknown* \$content, [*unknown* \$filter], [*unknown* \$attributes])

Adds a inline javascript to the collection

public *int* **count** ()

Returns the number of elements in the form

public **rewind** ()

Rewinds the internal iterator

public **Phalcon\Assets\Resource current** ()

Returns the current resource in the iterator

public *int* **key** ()

Returns the current position/key in the iterator

public **next** ()

Moves the internal iteration pointer to the next position

public *boolean* **valid** ()

Check if the current element in the iterator is valid

public **Phalcon\Assets\Collection setTargetPath** (*string* \$targetPath)

Sets the target path of the file for the filtered/join output

public **Phalcon\Assets\Collection setSourcePath** (*string* \$sourcePath)

Sets a base source path for all the resources in this collection

public **Phalcon\Assets\Collection setTargetUri** (*string* \$targetUri)

Sets a target uri for the generated HTML

public **Phalcon\Assets\Collection setPrefix** (*string* \$prefix)

Sets a common prefix for all the resources

public **Phalcon\Assets\Collection setLocal** (*boolean* \$local)

Sets if the collection uses local resources by default

public *\$this* **setAttributes** (*array* \$attributes)

Sets extra HTML attributes

public **Phalcon\Assets\Collection setFilters** (*array* \$filters)

Sets an array of filters in the collection

public **Phalcon\Assets\Collection setTargetLocal** (*boolean* \$targetLocal)

Sets the target local

public **Phalcon\Assets\Collection join** (*unknown* \$join)

Sets if all filtered resources in the collection must be joined in a single result file

public *string* **getRealTargetPath** (*unknown* \$basePath)

Returns the complete location where the joined/filtered collection must be written

`public Phalcon\Assets\Collection addFilter (unknown $filter)`

Adds a filter to the collection

`public __construct ()`

...

2.58.18 Class Phalcon\Assets\Exception

extends class Phalcon\Exception

Methods

`final private Exception __clone ()` inherited from `Exception`

Clone the exception

`public __construct ([string $message], [int $code], [Exception $previous])` inherited from `Exception`

Exception constructor

`final public string getMessage ()` inherited from `Exception`

Gets the Exception message

`final public int getCode ()` inherited from `Exception`

Gets the Exception code

`final public string getFile ()` inherited from `Exception`

Gets the file in which the exception occurred

`final public int getLine ()` inherited from `Exception`

Gets the line in which the exception occurred

`final public array getTrace ()` inherited from `Exception`

Gets the stack trace

`final public Exception getPrevious ()` inherited from `Exception`

Returns previous Exception

`final public Exception getTraceAsString ()` inherited from `Exception`

Gets the stack trace as a string

`public string __toString ()` inherited from `Exception`

String representation of the exception

2.58.19 Class Phalcon\Assets\Filters\Cssmin

implements Phalcon\Assets\FilterInterface

Minify the css - removes comments removes newlines and line feeds keeping removes last semicolon from last property

Methods

public *string* **filter** (*unknown* \$content)

Filters the content using CSSMIN

2.58.20 Class Phalcon\Assets\Filters\Jsmin

implements [Phalcon\Assets\FilterInterface](#)

Deletes the characters which are insignificant to JavaScript. Comments will be removed. Tabs will be replaced with spaces. Carriage returns will be replaced with linefeeds. Most spaces and linefeeds will be removed.

Methods

public *string* **filter** (*unknown* \$content)

Filters the content using JSMIN

2.58.21 Class Phalcon\Assets\Filters\None

implements [Phalcon\Assets\FilterInterface](#)

Returns the content without make any modification to the original source

Methods

public *string* **filter** (*unknown* \$content)

Returns the content without be touched

2.58.22 Class Phalcon\Assets\Inline

Represents an inline asset

```
<?php  
  
$inline = new \Phalcon\Assets\Inline('js', 'alert("hello world");');
```

Methods

public **getType** ()

...

public **getContent** ()

...

public **getFilter** ()

...

public **getAttributes** ()

...

public **__construct** (*unknown* \$type, *unknown* \$content, [*unknown* \$filter], [*unknown* \$attributes])

Phalcon\Assets\Inline constructor

public [Phalcon\Assets\Inline](#) **setType** (*unknown* \$type)

Sets the inline's type

public [Phalcon\Assets\Inline](#) **setFilter** (*unknown* \$filter)

Sets if the resource must be filtered or not

public [Phalcon\Assets\Inline](#) **setAttributes** (*unknown* \$attributes)

Sets extra HTML attributes

2.58.23 Class Phalcon\Assets\Inline\Css

extends class [Phalcon\Assets\Inline](#)

Represents inline CSS

Methods

public **__construct** (*unknown* \$content, [*unknown* \$filter], [*unknown* \$attributes])

public **getType** () inherited from [Phalcon\Assets\Inline](#)

...

public **getContent** () inherited from [Phalcon\Assets\Inline](#)

...

public **getFilter** () inherited from [Phalcon\Assets\Inline](#)

...

public **getAttributes** () inherited from [Phalcon\Assets\Inline](#)

...

public [Phalcon\Assets\Inline](#) **setType** (*unknown* \$type) inherited from [Phalcon\Assets\Inline](#)

Sets the inline's type

public [Phalcon\Assets\Inline](#) **setFilter** (*unknown* \$filter) inherited from [Phalcon\Assets\Inline](#)

Sets if the resource must be filtered or not

public [Phalcon\Assets\Inline](#) **setAttributes** (*unknown* \$attributes) inherited from [Phalcon\Assets\Inline](#)

Sets extra HTML attributes

2.58.24 Class Phalcon\Assets\Inline\Js

extends class [Phalcon\Assets\Inline](#)

Represents inline Javascript

Methods

public **__construct** (*unknown* \$content, [*unknown* \$filter], [*unknown* \$attributes])

public **getType** () inherited from Phalcon\Assets\Inline

...

public **getContent** () inherited from Phalcon\Assets\Inline

...

public **getFilter** () inherited from Phalcon\Assets\Inline

...

public **getAttributes** () inherited from Phalcon\Assets\Inline

...

public **Phalcon\Assets\Inline setType** (*unknown* \$type) inherited from Phalcon\Assets\Inline

Sets the inline's type

public **Phalcon\Assets\Inline setFilter** (*unknown* \$filter) inherited from Phalcon\Assets\Inline

Sets if the resource must be filtered or not

public **Phalcon\Assets\Inline setAttributes** (*unknown* \$attributes) inherited from Phalcon\Assets\Inline

Sets extra HTML attributes

2.58.25 Class Phalcon\Assets\Manager

Manages collections of CSS/Javascript assets

Methods

public **__construct** ([*unknown* \$options])

public **Phalcon\Assets\Manager setOptions** (*unknown* \$options)

Sets the manager options

public **array getOptions** ()

Returns the manager options

public **Phalcon\Assets\Manager useImplicitOutput** (*unknown* \$implicitOutput)

Sets if the HTML generated must be directly printed or returned

public **Phalcon\Assets\Manager addCss** (*unknown* \$path, [*unknown* \$local], [*unknown* \$filter], [*unknown* \$attributes])

Adds a Css resource to the 'css' collection

```
<?php  
  
$assets->addCss('css/bootstrap.css');  
$assets->addCss('http://bootstrap.my-cdn.com/style.css', false);
```

public Phalcon\Assets\Manager addInlineCss (*unknown \$content, [unknown \$filter], [unknown \$attributes]*)

Adds a inline Css to the ‘css’ collection

public Phalcon\Assets\Manager addJs (*unknown \$path, [unknown \$local], [unknown \$filter], [unknown \$attributes]*)

Adds a javascript resource to the ‘js’ collection

```
<?php
```

```
$assets->addJs('scripts/jquery.js');
$assets->addJs('http://jquery.my-cdn.com/jquery.js', false);
```

public Phalcon\Assets\Manager addInlineJs (*unknown \$content, [unknown \$filter], [unknown \$attributes]*)

Adds a inline javascript to the ‘js’ collection

public Phalcon\Assets\Manager addResourceByType (*unknown \$type, unknown \$resource*)

Adds a resource by its type

```
<?php
```

```
$assets->addResourceByType('css', new \Phalcon\Assets\Resource\Css('css/style.css'));
```

public Phalcon\Assets\Manager addInlineCodeByType (*unknown \$type, unknown \$code*)

Adds a inline code by its type

public Phalcon\Assets\Manager addResource (*Phalcon\Assets\Resource \$resource*)

Adds a raw resource to the manager

```
<?php
```

```
$assets->addResource(new Phalcon\Assets\Resource('css', 'css/style.css'));
```

public Phalcon\Assets\Manager addInlineCode (*unknown \$code*)

Adds a raw inline code to the manager

public Phalcon\Assets\Manager set (*unknown \$id, unknown \$collection*)

Sets a collection in the Assets Manager

```
<?php
```

```
$assets->set('js', $collection);
```

public Phalcon\Assets\Collection get (*unknown \$id*)

Returns a collection by its id

```
<?php
```

```
$scripts = $assets->get('js');
```

public Phalcon\Assets\Collection getCss ()

Returns the CSS collection of assets

public Phalcon\Assets\Collection getJs ()

Returns the CSS collection of assets

public Phalcon\Assets\Collection collection (*unknown \$name*)

Creates/Returns a collection of resources

public **output** (*unknown* \$collection, *unknown* \$callback, *unknown* \$type)

Traverses a collection calling the callback to generate its HTML

public **outputInline** (*unknown* \$collection, *unknown* \$type)

Traverses a collection and generate its HTML

public **outputCss** ([*unknown* \$collectionName])

Prints the HTML for CSS resources

public **outputInlineCss** ([*unknown* \$collectionName])

Prints the HTML for inline CSS

public **outputJs** ([*unknown* \$collectionName])

Prints the HTML for JS resources

public **outputInlineJs** ([*unknown* \$collectionName])

Prints the HTML for inline JS

2.58.26 Class Phalcon\Assets\Resource

Represents an asset resource

```
<?php  
  
$resource = new \Phalcon\Assets\Resource('js', 'javascripts/jquery.js');
```

Methods

public **getType** ()

...

public **getPath** ()

...

public **getLocal** ()

...

public **getFilter** ()

...

public **getAttributes** ()

...

public **getSourcePath** ()

...

public **getTargetPath** ()

...

public **getTargetUri** ()

...

public **__construct** (*unknown* \$type, *unknown* \$path, [*unknown* \$local], [*unknown* \$filter], [*unknown* \$attributes])

Phalcon\Assets\Resource constructor

public [Phalcon\Assets\Resource](#) **setType** (*unknown* \$type)

Sets the resource's type

public [Phalcon\Assets\Resource](#) **setPath** (*unknown* \$path)

Sets the resource's path

public [Phalcon\Assets\Resource](#) **setLocal** (*unknown* \$local)

Sets if the resource is local or external

public [Phalcon\Assets\Resource](#) **setFilter** (*unknown* \$filter)

Sets if the resource must be filtered or not

public [Phalcon\Assets\Resource](#) **setAttributes** (*unknown* \$attributes)

Sets extra HTML attributes

public [Phalcon\Assets\Resource](#) **setTargetUri** (*unknown* \$targetUri)

Sets a target uri for the generated HTML

public [Phalcon\Assets\Resource](#) **setSourcePath** (*unknown* \$sourcePath)

Sets the resource's source path

public [Phalcon\Assets\Resource](#) **setTargetPath** (*unknown* \$targetPath)

Sets the resource's target path

public *string* **getContent** ([*unknown* \$basePath])

Returns the content of the resource as an string Optionally a base path where the resource is located can be set

public *string* **getRealTargetUri** ()

Returns the real target uri for the generated HTML

public *string* **getRealSourcePath** ([*unknown* \$basePath])

Returns the complete location where the resource is located

public *string* **getRealTargetPath** ([*unknown* \$basePath])

Returns the complete location where the resource must be written

2.58.27 Class Phalcon\Assets\Resource\Css

extends class [Phalcon\Assets\Resource](#)

Represents CSS resources

Methods

public **__construct** (*unknown* \$path, [*unknown* \$local], [*unknown* \$filter], [*unknown* \$attributes])

public **getType** () inherited from [Phalcon\Assets\Resource](#)

...

public **getPath** () inherited from Phalcon\Assets\Resource
...
public **getLocal** () inherited from Phalcon\Assets\Resource
...
public **getFilter** () inherited from Phalcon\Assets\Resource
...
public **getAttributes** () inherited from Phalcon\Assets\Resource
...
public **getSourcePath** () inherited from Phalcon\Assets\Resource
...
public **getTargetPath** () inherited from Phalcon\Assets\Resource
...
public **getTargetUri** () inherited from Phalcon\Assets\Resource
...
public **Phalcon\Assets\Resource setType** (*unknown \$type*) inherited from Phalcon\Assets\Resource
Sets the resource's type
public **Phalcon\Assets\Resource setPath** (*unknown \$path*) inherited from Phalcon\Assets\Resource
Sets the resource's path
public **Phalcon\Assets\Resource setLocal** (*unknown \$local*) inherited from Phalcon\Assets\Resource
Sets if the resource is local or external
public **Phalcon\Assets\Resource setFilter** (*unknown \$filter*) inherited from Phalcon\Assets\Resource
Sets if the resource must be filtered or not
public **Phalcon\Assets\Resource setAttributes** (*unknown \$attributes*) inherited from Phalcon\Assets\Resource
Sets extra HTML attributes
public **Phalcon\Assets\Resource setTargetUri** (*unknown \$targetUri*) inherited from Phalcon\Assets\Resource
Sets a target uri for the generated HTML
public **Phalcon\Assets\Resource setSourcePath** (*unknown \$sourcePath*) inherited from Phalcon\Assets\Resource
Sets the resource's source path
public **Phalcon\Assets\Resource setTargetPath** (*unknown \$targetPath*) inherited from Phalcon\Assets\Resource
Sets the resource's target path
public **string getContent** ([*unknown \$basePath*]) inherited from Phalcon\Assets\Resource
Returns the content of the resource as an string Optionally a base path where the resource is located can be set
public **string getRealTargetUri** () inherited from Phalcon\Assets\Resource
Returns the real target uri for the generated HTML
public **string getRealSourcePath** ([*unknown \$basePath*]) inherited from Phalcon\Assets\Resource
Returns the complete location where the resource is located

public **string getRealTargetPath** ([*unknown \$basePath*]) inherited from Phalcon\Assets\Resource

Returns the complete location where the resource must be written

2.58.28 Class Phalcon\Assets\Resource\Js

extends class Phalcon\Assets\Resource

Represents Javascript resources

Methods

public **__construct** (*unknown \$path*, [*unknown \$local*], [*unknown \$filter*], [*unknown \$attributes*])

public **getType** () inherited from Phalcon\Assets\Resource

...

public **getPath** () inherited from Phalcon\Assets\Resource

...

public **getLocal** () inherited from Phalcon\Assets\Resource

...

public **getFilter** () inherited from Phalcon\Assets\Resource

...

public **getAttributes** () inherited from Phalcon\Assets\Resource

...

public **getSourcePath** () inherited from Phalcon\Assets\Resource

...

public **getTargetPath** () inherited from Phalcon\Assets\Resource

...

public **getTargetUri** () inherited from Phalcon\Assets\Resource

...

public **Phalcon\Assets\Resource setType** (*unknown \$type*) inherited from Phalcon\Assets\Resource

Sets the resource's type

public **Phalcon\Assets\Resource setPath** (*unknown \$path*) inherited from Phalcon\Assets\Resource

Sets the resource's path

public **Phalcon\Assets\Resource setLocal** (*unknown \$local*) inherited from Phalcon\Assets\Resource

Sets if the resource is local or external

public **Phalcon\Assets\Resource setFilter** (*unknown \$filter*) inherited from Phalcon\Assets\Resource

Sets if the resource must be filtered or not

public **Phalcon\Assets\Resource setAttributes** (*unknown \$attributes*) inherited from Phalcon\Assets\Resource

Sets extra HTML attributes

public **Phalcon\Assets\Resource setTargetUri** (*unknown \$targetUri*) inherited from Phalcon\Assets\Resource

Sets a target uri for the generated HTML

public **Phalcon\Assets\Resource** **setSourcePath** (*unknown* \$sourcePath) inherited from Phalcon\Assets\Resource

Sets the resource's source path

public **Phalcon\Assets\Resource** **setTargetPath** (*unknown* \$targetPath) inherited from Phalcon\Assets\Resource

Sets the resource's target path

public *string* **getContent** ([*unknown* \$basePath]) inherited from Phalcon\Assets\Resource

Returns the content of the resource as an string Optionally a base path where the resource is located can be set

public *string* **getRealTargetUri** () inherited from Phalcon\Assets\Resource

Returns the real target uri for the generated HTML

public *string* **getRealSourcePath** ([*unknown* \$basePath]) inherited from Phalcon\Assets\Resource

Returns the complete location where the resource is located

public *string* **getRealTargetPath** ([*unknown* \$basePath]) inherited from Phalcon\Assets\Resource

Returns the complete location where the resource must be written

2.58.29 Abstract class Phalcon\Cache\Backend

This class implements common functionality for backend adapters. A backend cache adapter may extend this class

Methods

public **getFrontend** ()

...

public **setFrontend** (*unknown* \$frontend)

...

public **getOptions** ()

...

public **setOptions** (*unknown* \$options)

...

public **getLastKey** ()

...

public **setLastKey** (*unknown* \$lastKey)

...

public **__construct** (*unknown* \$frontend, [*unknown* \$options])

Phalcon\Cache\Backend constructor

public *mixed* **start** (*unknown* \$keyName, [*unknown* \$lifetime])

Starts a cache. The keyname allows to identify the created fragment

public **stop** ([*unknown* \$stopBuffer])

Stops the frontend without store any cached content

`public boolean isFresh ()`

Checks whether the last cache is fresh or cached

`public boolean isStarted ()`

Checks whether the cache has starting buffering or not

`public int getLifetime ()`

Gets the last lifetime set

2.58.30 Class Phalcon\Cache\Backend\Apc

extends abstract class `Phalcon\Cache\Backend`

implements `Phalcon\Cache\BackendInterface`

Allows to cache output fragments, PHP data and raw data using an APC backend

```
<?php

//Cache data for 2 days
$frontCache = new \Phalcon\Cache\Frontend\Data(array(
    'lifetime' => 172800
));

$cache = new \Phalcon\Cache\Backend\Apc($frontCache, array(
    'prefix' => 'app-data'
));

//Cache arbitrary data
$cache->save('my-data', array(1, 2, 3, 4, 5));

//Get data
$data = $cache->get('my-data');
```

Methods

`public mixed get (unknown $keyName, [unknown $lifetime])`

Returns a cached content

`public save ([unknown $keyName], [unknown $content], [unknown $lifetime], [unknown $stopBuffer])`

Stores cached content into the APC backend and stops the frontend

`public mixed increment ([unknown $keyName], [unknown $value])`

Increment of a given key, by number \$value

`public mixed decrement ([unknown $keyName], [unknown $value])`

Decrement of a given key, by number \$value

`public boolean delete (unknown $keyName)`

Deletes a value from the cache by its key

`public array queryKeys ([unknown $prefix])`

Query the existing cached keys

public *boolean exists* ([*unknown \$keyName*], [*unknown \$lifetime*])

Checks if cache exists and it hasn't expired

public **getFrontend** () inherited from Phalcon\Cache\Backend

...

public **setFrontend** (*unknown \$frontend*) inherited from Phalcon\Cache\Backend

...

public **getOptions** () inherited from Phalcon\Cache\Backend

...

public **setOptions** (*unknown \$options*) inherited from Phalcon\Cache\Backend

...

public **getLastKey** () inherited from Phalcon\Cache\Backend

...

public **setLastKey** (*unknown \$lastKey*) inherited from Phalcon\Cache\Backend

...

public **__construct** (*unknown \$frontend*, [*unknown \$options*]) inherited from Phalcon\Cache\Backend

Phalcon\Cache\Backend constructor

public *mixed start* (*unknown \$keyName*, [*unknown \$lifetime*]) inherited from Phalcon\Cache\Backend

Starts a cache. The keyname allows to identify the created fragment

public **stop** ([*unknown \$stopBuffer*]) inherited from Phalcon\Cache\Backend

Stops the frontend without store any cached content

public *boolean isFresh* () inherited from Phalcon\Cache\Backend

Checks whether the last cache is fresh or cached

public *boolean isStarted* () inherited from Phalcon\Cache\Backend

Checks whether the cache has starting buffering or not

public *int getLifetime* () inherited from Phalcon\Cache\Backend

Gets the last lifetime set

2.58.31 Class Phalcon\Cache\Backend\File

extends abstract class Phalcon\Cache\Backend

implements Phalcon\Cache\BackendInterface

Allows to cache output fragments using a file backend

```
<?php

//Cache the file for 2 days
$frontendOptions = array(
    'lifetime' => 172800
);
```

```

//Create a output cache
$frontCache = \Phalcon\Cache\Frontend\Output($frontOptions);

//Set the cache directory
$backendOptions = array(
    'cacheDir' => '../app/cache/'
);

//Create the File backend
$cache = new \Phalcon\Cache\Backend\File($frontCache, $backendOptions);

$content = $cache->start('my-cache');
if ($content === null) {
    echo '<h1>', time(), '</h1>';
    $cache->save();
} else {
    echo $content;
}

```

Methods

public __construct (unknown \$frontend, [unknown \$options])

Phalcon\Cache\Backend\File constructor

public mixed get (unknown \$keyName, [unknown \$lifetime])

Returns a cached content

public save ([unknown \$keyName], [unknown \$content], [unknown \$lifetime], [unknown \$stopBuffer])

Stores cached content into the file backend and stops the frontend

public boolean delete (unknown \$keyName)

Deletes a value from the cache by its key

public array queryKeys ([unknown \$prefix])

Query the existing cached keys

public boolean exists ([unknown \$keyName], [unknown \$lifetime])

Checks if cache exists and it isn't expired

public mixed increment ([unknown \$keyName], [unknown \$value])

Increment of a given key, by number \$value

public mixed decrement ([unknown \$keyName], [unknown \$value])

Decrement of a given key, by number \$value

public boolean flush ()

Immediately invalidates all existing items.

public string getKey (unknown \$key)

Return a file-system safe identifier for a given key

public this useSafeKey (unknown \$useSafeKey)

Set whether to use the safekey or not

public **getFrontend** () inherited from Phalcon\Cache\Backend
...
public **setFrontend** (*unknown* \$frontend) inherited from Phalcon\Cache\Backend
...
public **getOptions** () inherited from Phalcon\Cache\Backend
...
public **setOptions** (*unknown* \$options) inherited from Phalcon\Cache\Backend
...
public **getLastKey** () inherited from Phalcon\Cache\Backend
...
public **setLastKey** (*unknown* \$lastKey) inherited from Phalcon\Cache\Backend
...
public *mixed* **start** (*unknown* \$keyName, [*unknown* \$lifetime]) inherited from Phalcon\Cache\Backend
Starts a cache. The keyname allows to identify the created fragment
public **stop** ([*unknown* \$stopBuffer]) inherited from Phalcon\Cache\Backend
Stops the frontend without store any cached content
public *boolean* **isFresh** () inherited from Phalcon\Cache\Backend
Checks whether the last cache is fresh or cached
public *boolean* **isStarted** () inherited from Phalcon\Cache\Backend
Checks whether the cache has starting buffering or not
public *int* **getLifetime** () inherited from Phalcon\Cache\Backend
Gets the last lifetime set

2.58.32 Class Phalcon\Cache\Backend\Libmemcached

extends abstract class Phalcon\Cache\Backend

implements Phalcon\Cache\BackendInterface

Allows to cache output fragments, PHP data or raw data to a libmemcached backend This adapter uses the special memcached key “_PHCM” to store all the keys internally used by the adapter

```
<?php

// Cache data for 2 days
$frontCache = new \Phalcon\Cache\Frontend\Data(array(
    "lifetime" => 172800
));

//Create the Cache setting memcached connection options
$cache = new \Phalcon\Cache\Backend\Libmemcached($frontCache, array(
    "servers" => array(
        array('host' => 'localhost',
              'port' => 11211,
              'weight' => 1),
    )
));
```

```

),
"client" => array(
    Memcached::OPT_HASH => Memcached::HASH_MD5,
    Memcached::OPT_PREFIX_KEY => 'prefix.',
)
);

//Cache arbitrary data
$cache->save('my-data', array(1, 2, 3, 4, 5));

//Get data
$data = $cache->get('my-data');

```

Methods

public __construct (*unknown* \$frontend, [*unknown* \$options])

Phalcon\Cache\Backend\Memcache constructor

public _connect ()

Create internal connection to memcached

public mixed get (*unknown* \$keyName, [*unknown* \$lifetime])

Returns a cached content

public save ([*unknown* \$keyName], [*unknown* \$content], [*unknown* \$lifetime], [*unknown* \$stopBuffer])

Stores cached content into the file backend and stops the frontend

public boolean delete (*unknown* \$keyName)

Deletes a value from the cache by its key

public array queryKeys ([*unknown* \$prefix])

Query the existing cached keys

public boolean exists ([*unknown* \$keyName], [*unknown* \$lifetime])

Checks if cache exists and it isn't expired

public long increment ([*unknown* \$keyName], [*unknown* \$value])

Increment of given \$keyName by \$value

public long decrement ([*unknown* \$keyName], [*unknown* \$value])

Decrement of \$keyName by given \$value

public boolean flush ()

Immediately invalidates all existing items.

public getFrontend () inherited from Phalcon\Cache\Backend

...

public setFrontend (*unknown* \$frontend) inherited from Phalcon\Cache\Backend

...

public getOptions () inherited from Phalcon\Cache\Backend

...

public **setOptions** (*unknown* \$options) inherited from Phalcon\Cache\Backend

...

public **getLastKey** () inherited from Phalcon\Cache\Backend

...

public **setLastKey** (*unknown* \$lastKey) inherited from Phalcon\Cache\Backend

...

public *mixed* **start** (*unknown* \$keyName, [*unknown* \$lifetime]) inherited from Phalcon\Cache\Backend

Starts a cache. The keyname allows to identify the created fragment

public **stop** ([*unknown* \$stopBuffer]) inherited from Phalcon\Cache\Backend

Stops the frontend without store any cached content

public *boolean* **isFresh** () inherited from Phalcon\Cache\Backend

Checks whether the last cache is fresh or cached

public *boolean* **isStarted** () inherited from Phalcon\Cache\Backend

Checks whether the cache has starting buffering or not

public *int* **getLifetime** () inherited from Phalcon\Cache\Backend

Gets the last lifetime set

2.58.33 Class Phalcon\Cache\Backend\Memcache

extends abstract class Phalcon\Cache\Backend

implements Phalcon\Cache\BackendInterface

Allows to cache output fragments, PHP data or raw data to a memcache backend This adapter uses the special memcached key “_PHCM” to store all the keys internally used by the adapter

```
<?php

// Cache data for 2 days
$frontCache = new \Phalcon\Cache\Frontend\Data(array(
    "lifetime" => 172800
));

//Create the Cache setting memcached connection options
$cache = new \Phalcon\Cache\Backend\Memcache($frontCache, array(
    'host' => 'localhost',
    'port' => 11211,
    'persistent' => false
));

//Cache arbitrary data
$cache->save('my-data', array(1, 2, 3, 4, 5));

//Get data
$data = $cache->get('my-data');
```

Methods

public **__construct** (*unknown* \$frontend, [*unknown* \$options])

Phalcon\Cache\Backend\Memcache constructor

public **_connect** ()

Create internal connection to memcached

public **mixed get** (*unknown* \$keyName, [*unknown* \$lifetime])

Returns a cached content

public **save** ([*unknown* \$keyName], [*unknown* \$content], [*unknown* \$lifetime], [*unknown* \$stopBuffer])

Stores cached content into the file backend and stops the frontend

public **boolean delete** (*unknown* \$keyName)

Deletes a value from the cache by its key

public **array queryKeys** ([*unknown* \$prefix])

Query the existing cached keys

public **boolean exists** (*unknown* \$keyName), [*unknown* \$lifetime])

Checks if cache exists and it isn't expired

public **long increment** (*unknown* \$keyName), [*unknown* \$value])

Increment of given \$keyName by \$value

public **long decrement** (*unknown* \$keyName), [*unknown* \$value])

Decrement of \$keyName by given \$value

public **boolean flush** ()

Immediately invalidates all existing items.

public **getFrontend** () inherited from Phalcon\Cache\Backend

...

public **setFrontend** (*unknown* \$frontend) inherited from Phalcon\Cache\Backend

...

public **getOptions** () inherited from Phalcon\Cache\Backend

...

public **setOptions** (*unknown* \$options) inherited from Phalcon\Cache\Backend

...

public **getLastKey** () inherited from Phalcon\Cache\Backend

...

public **setLastKey** (*unknown* \$lastKey) inherited from Phalcon\Cache\Backend

...

public **mixed start** (*unknown* \$keyName, [*unknown* \$lifetime]) inherited from Phalcon\Cache\Backend

Starts a cache. The keyname allows to identify the created fragment

public **stop** ([*unknown* \$stopBuffer]) inherited from Phalcon\Cache\Backend

Stops the frontend without store any cached content

`public boolean isFresh ()` inherited from Phalcon\Cache\Backend

Checks whether the last cache is fresh or cached

`public boolean isStarted ()` inherited from Phalcon\Cache\Backend

Checks whether the cache has starting buffering or not

`public int getLifetime ()` inherited from Phalcon\Cache\Backend

Gets the last lifetime set

2.58.34 Class Phalcon\Cache\Backend\Memory

extends abstract class Phalcon\Cache\Backend

implements Phalcon\Cache\BackendInterface

Stores content in memory. Data is lost when the request is finished

```
<?php

//Cache data
$frontCache = new \Phalcon\Cache\Frontend\Data();

$cache = new \Phalcon\Cache\Backend\Memory($frontCache);

//Cache arbitrary data
$cache->save('my-data', array(1, 2, 3, 4, 5));

//Get data
$data = $cache->get('my-data');
```

Methods

`public mixed get (unknown $keyName, [unknown $lifetime])`

Returns a cached content

`public save ([unknown $keyName], [unknown $content], [unknown $lifetime], [unknown $stopBuffer])`

Stores cached content into the backend and stops the frontend

`public boolean delete (unknown $keyName)`

Deletes a value from the cache by its key

`public array queryKeys ([unknown $prefix])`

Query the existing cached keys

`public boolean exists ([unknown $keyName], [unknown $lifetime])`

Checks if cache exists and it hasn't expired

`public long increment ([unknown $keyName], [unknown $value])`

Increment of given \$keyName by \$value

`public long decrement ([unknown $keyName], [unknown $value])`

Decrement of \$keyName by given \$value

```

public boolean flush ()
Immediately invalidates all existing items.

public getFrontend () inherited from Phalcon\Cache\Backend
...
public setFrontend (unknown $frontend) inherited from Phalcon\Cache\Backend
...
public getOptions () inherited from Phalcon\Cache\Backend
...
public setOptions (unknown $options) inherited from Phalcon\Cache\Backend
...
public getLastKey () inherited from Phalcon\Cache\Backend
...
public setLastKey (unknown $lastKey) inherited from Phalcon\Cache\Backend
...
public __construct (unknown $frontend, [unknown $options]) inherited from Phalcon\Cache\Backend
Phalcon\Cache\Backend constructor
public mixed start (unknown $keyName, [unknown $lifetime]) inherited from Phalcon\Cache\Backend
Starts a cache. The keyname allows to identify the created fragment
public stop ([unknown $stopBuffer]) inherited from Phalcon\Cache\Backend
Stops the frontend without store any cached content
public boolean isFresh () inherited from Phalcon\Cache\Backend
Checks whether the last cache is fresh or cached
public boolean isStarted () inherited from Phalcon\Cache\Backend
Checks whether the cache has starting buffering or not
public int getLifetime () inherited from Phalcon\Cache\Backend
Gets the last lifetime set

```

2.58.35 Class Phalcon\Cache\Backend\Mongo

extends abstract class Phalcon\Cache\Backend
implements Phalcon\Cache\BackendInterface

Allows to cache output fragments, PHP data or raw data to a MongoDB backend

```

<?php

// Cache data for 2 days
$frontCache = new \Phalcon\Cache\Frontend\Base64 (array (
    "lifetime" => 172800
));

```

```
//Create a MongoDB cache
$cache = new \Phalcon\Cache\Backend\Mongo($frontCache, array(
    'server' => "mongodb://localhost",
    'db' => 'caches',
    'collection' => 'images'
));

//Cache arbitrary data
$cache->save('my-data', file_get_contents('some-image.jpg'));

//Get data
$data = $cache->get('my-data');
```

Methods

public __construct (*unknown* \$frontend, [*unknown* \$options])

Phalcon\Cache\Backend\Mongo constructor

public *MongoCollection* _getCollection ()

Returns a MongoDB collection based on the backend parameters

public *mixed* get (*unknown* \$keyName, [*unknown* \$lifetime])

Returns a cached content

public *save* ([*unknown* \$keyName], [*unknown* \$content], [*unknown* \$lifetime], [*unknown* \$stopBuffer])

Stores cached content into the file backend and stops the frontend

public *boolean* delete (*unknown* \$keyName)

Deletes a value from the cache by its key

public *array* queryKeys ([*unknown* \$prefix])

Query the existing cached keys

public *boolean* exists (*unknown* \$keyName), [*unknown* \$lifetime])

Checks if cache exists and it isn't expired

public *collection->remove(...)* gc ()

gc

public *mixed* increment (*unknown* \$keyName, [*unknown* \$value])

Increment of a given key by \$value

public *mixed* decrement (*int|string* \$keyName, [*long* \$value])

Decrement of a given key by \$value

public *bool* flush ()

Immediately invalidates all existing items.

public *getFrontend* () inherited from Phalcon\Cache\Backend

...

public *setFrontend* (*unknown* \$frontend) inherited from Phalcon\Cache\Backend

...

```

public getOptions () inherited from Phalcon\Cache\Backend
...
public setOptions (unknown $options) inherited from Phalcon\Cache\Backend
...
public getLastKey () inherited from Phalcon\Cache\Backend
...
public setLastKey (unknown $lastKey) inherited from Phalcon\Cache\Backend
...
public mixed start (unknown $keyName, [unknown $lifetime]) inherited from Phalcon\Cache\Backend
Starts a cache. The keyname allows to identify the created fragment
public stop ([unknown $stopBuffer]) inherited from Phalcon\Cache\Backend
Stops the frontend without store any cached content
public boolean isFresh () inherited from Phalcon\Cache\Backend
Checks whether the last cache is fresh or cached
public boolean isStarted () inherited from Phalcon\Cache\Backend
Checks whether the cache has starting buffering or not
public int getLifetime () inherited from Phalcon\Cache\Backend
Gets the last lifetime set

```

2.58.36 Class Phalcon\Cache\Backend\Redis

extends abstract class Phalcon\Cache\Backend

implements Phalcon\Cache\BackendInterface

Allows to cache output fragments, PHP data or raw data to a redis backend This adapter uses the special redis key “_PHCR” to store all the keys internally used by the adapter

```

<?php

// Cache data for 2 days
$frontCache = new \Phalcon\Cache\Frontend\Data(array(
    "lifetime" => 172800
));

//Create the Cache setting redis connection options
$cache = new Phalcon\Cache\Backend\Redis($frontCache, array(
    'host' => 'localhost',
    'port' => 6379,
    'auth' => 'foobared',
    'persistent' => false
));
//Cache arbitrary data
$cache->save('my-data', array(1, 2, 3, 4, 5));

```

```
//Get data
$data = $cache->get('my-data');
```

Methods

public **__construct** (*unknown* \$frontend, [*unknown* \$options])

Phalcon\Cache\Backend\Redis constructor

public **_connect** ()

Create internal connection to redis

public **mixed get** (*unknown* \$keyName, [*unknown* \$lifetime])

Returns a cached content

public **save** ([*unknown* \$keyName], [*unknown* \$content], [*unknown* \$lifetime], [*unknown* \$stopBuffer])

Stores cached content into the file backend and stops the frontend

public **boolean delete** (*unknown* \$keyName)

Deletes a value from the cache by its key

public **array queryKeys** ([*unknown* \$prefix])

Query the existing cached keys

public **boolean exists** ([*unknown* \$keyName], [*unknown* \$lifetime])

Checks if cache exists and it isn't expired

public **long increment** ([*unknown* \$keyName], [*unknown* \$value])

Increment of given \$keyName by \$value

public **long decrement** ([*unknown* \$keyName], [*unknown* \$value])

Decrement of \$keyName by given \$value

public **boolean flush** ()

Immediately invalidates all existing items.

public **getFrontend** () inherited from Phalcon\Cache\Backend

...

public **setFrontend** (*unknown* \$frontend) inherited from Phalcon\Cache\Backend

...

public **getOptions** () inherited from Phalcon\Cache\Backend

...

public **setOptions** (*unknown* \$options) inherited from Phalcon\Cache\Backend

...

public **getLastKey** () inherited from Phalcon\Cache\Backend

...

public **setLastKey** (*unknown* \$lastKey) inherited from Phalcon\Cache\Backend

...

public mixed start (*unknown \$keyName*, [*unknown \$lifetime*]) inherited from Phalcon\Cache\Backend

Starts a cache. The keyname allows to identify the created fragment

public stop ([*unknown \$stopBuffer*]) inherited from Phalcon\Cache\Backend

Stops the frontend without store any cached content

public boolean isFresh () inherited from Phalcon\Cache\Backend

Checks whether the last cache is fresh or cached

public boolean isStarted () inherited from Phalcon\Cache\Backend

Checks whether the cache has starting buffering or not

public int getLifetime () inherited from Phalcon\Cache\Backend

Gets the last lifetime set

2.58.37 Class Phalcon\Cache\Backend\Xcache

extends abstract class Phalcon\Cache\Backend

implements Phalcon\Cache\BackendInterface

Allows to cache output fragments, PHP data and raw data using an XCache backend

```
<?php

//Cache data for 2 days
$frontCache = new \Phalcon\Cache\Frontend\Data(array(
    'lifetime' => 172800
));

$cache = new \Phalcon\Cache\Backend\Xcache($frontCache, array(
    'prefix' => 'app-data'
));

//Cache arbitrary data
$cache->save('my-data', array(1, 2, 3, 4, 5));

//Get data
$data = $cache->get('my-data');
```

Methods

public __construct (*unknown \$frontend*, [*unknown \$options*])

Phalcon\Cache\Backend\Xcache constructor

public mixed get (*unknown \$keyName*, [*unknown \$lifetime*])

Returns a cached content

public save ([*unknown \$keyName*], [*unknown \$content*], [*unknown \$lifetime*], [*unknown \$stopBuffer*])

Stores cached content into the file backend and stops the frontend

public boolean delete (*unknown \$keyName*)

Deletes a value from the cache by its key

```
public array queryKeys ([unknown $prefix])
Query the existing cached keys

public boolean exists ([unknown $keyName], [unknown $lifetime])
Checks if cache exists and it isn't expired

public mixed increment (unknown $keyName, [unknown $value])
Atomic increment of a given key, by number $value

public mixed decrement (unknown $keyName, [unknown $value])
Atomic decrement of a given key, by number $value

public boolean flush ()
Immediately invalidates all existing items.

public getFrontend () inherited from Phalcon\Cache\Backend
...
public setFrontend (unknown $frontend) inherited from Phalcon\Cache\Backend
...
public getOptions () inherited from Phalcon\Cache\Backend
...
public setOptions (unknown $options) inherited from Phalcon\Cache\Backend
...
public getLastKey () inherited from Phalcon\Cache\Backend
...
public setLastKey (unknown $lastKey) inherited from Phalcon\Cache\Backend
...
public mixed start (unknown $keyName, [unknown $lifetime]) inherited from Phalcon\Cache\Backend
Starts a cache. The keyname allows to identify the created fragment

public stop ([unknown $stopBuffer]) inherited from Phalcon\Cache\Backend
Stops the frontend without store any cached content

public boolean isFresh () inherited from Phalcon\Cache\Backend
Checks whether the last cache is fresh or cached

public boolean isStarted () inherited from Phalcon\Cache\Backend
Checks whether the cache has starting buffering or not

public int getLifetime () inherited from Phalcon\Cache\Backend
Gets the last lifetime set
```

2.58.38 Class Phalcon\Cache\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from *Exception*
Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from *Exception*
Exception constructor

final public *string* **getMessage** () inherited from *Exception*
Gets the *Exception* message

final public *int* **getCode** () inherited from *Exception*
Gets the *Exception* code

final public *string* **getFile** () inherited from *Exception*
Gets the file in which the exception occurred

final public *int* **getLine** () inherited from *Exception*
Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from *Exception*
Gets the stack trace

final public *Exception* **getPrevious** () inherited from *Exception*
Returns previous *Exception*

final public *Exception* **getTraceAsString** () inherited from *Exception*
Gets the stack trace as a string

public *string* **__toString** () inherited from *Exception*
String representation of the exception

2.58.39 Class Phalcon\Cache\Frontend\Base64

implements [Phalcon\Cache\FrontendInterface](#)

Allows to cache data converting/deconverting them to base64. This adapter uses the base64_encode/base64_decode PHP's functions

```
<?php
<?php

// Cache the files for 2 days using a Base64 frontend
$frontCache = new \Phalcon\Cache\Frontend\Base64(array(
    "lifetime" => 172800
));

//Create a MongoDB cache
$cache = new \Phalcon\Cache\Backend\Mongo($frontCache, array(
    'server' => "mongodb://localhost",
    'db' => 'caches',
    'collection' => 'images'
));
```

```
// Try to get cached image
$cacheKey = 'some-image.jpg.cache';
$image    = $cache->get($cacheKey);
if ($image === null) {

    // Store the image in the cache
    $cache->save($cacheKey, file_get_contents('tmp-dir/some-image.jpg'));
}

header('Content-Type: image/jpeg');
echo $image;
```

Methods

public __construct ([*unknown* \$frontendOptions])

Phalcon\Cache\Frontend\Base64 constructor

public *integer* getLifetime ()

Returns the cache lifetime

public *boolean* isBuffering ()

Check whether if frontend is buffering output

public **start** ()

Starts output frontend. Actually, does nothing

public *string* getContent ()

Returns output cached content

public **stop** ()

Stops output frontend

public *string* beforeStore (*unknown* \$data)

Serializes data before storing them

public *mixed* afterRetrieve (*unknown* \$data)

Unserializes data after retrieval

2.58.40 Class Phalcon\Cache\Frontend\Data

implements Phalcon\Cache\FrontendInterface

Allows to cache native PHP data in a serialized form

```
<?php

<?php

// Cache the files for 2 days using a Data frontend
$frontCache = new \Phalcon\Cache\Frontend\Data(array(
    "lifetime" => 172800
));
```

```

// Create the component that will cache "Data" to a "File" backend
// Set the cache file directory - important to keep the "/" at the end of
// of the value for the folder
$cache = new \Phalcon\Cache\Backend\File($frontCache, array(
    "cacheDir" => "../app/cache/"
));

// Try to get cached records
$cacheKey = 'robots_order_id.cache';
$robots   = $cache->get($cacheKey);
if ($robots === null) {

    // $robots is null due to cache expiration or data does not exist
    // Make the database call and populate the variable
    $robots = Robots::find(array("order" => "id"));

    // Store it in the cache
    $cache->save($cacheKey, $robots);
}

// Use $robots :)
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}

```

Methods

public __construct ([*unknown* \$frontendOptions])

Phalcon\Cache\Frontend\Data constructor

public integer getLifetime ()

Returns the cache lifetime

public boolean isBuffering ()

Check whether if frontend is buffering output

public start ()

Starts output frontend. Actually, does nothing

public string getContent ()

Returns output cached content

public stop ()

Stops output frontend

public string beforeStore (*unknown* \$data)

Serializes data before storing them

public mixed afterRetrieve (*unknown* \$data)

Unserializes data after retrieval

2.58.41 Class Phalcon\Cache\Frontend\Igbinary

extends class Phalcon\Cache\Frontend\Data

implements Phalcon\Cache\FrontendInterface

Allows to cache native PHP data in a serialized form using igbinary extension

```
<?php

// Cache the files for 2 days using Igbinary frontend
$frontCache = new \Phalcon\Cache\Frontend\Igbinary(array(
    "lifetime" => 172800
));

// Create the component that will cache "Igbinary" to a "File" backend
// Set the cache file directory - important to keep the "/" at the end of
// of the value for the folder
$cache = new \Phalcon\Cache\Backend\File($frontCache, array(
    "cacheDir" => "../app/cache/"
));

// Try to get cached records
$cacheKey = 'robots_order_id.cache';
$robots = $cache->get($cacheKey);
if ($robots === null) {

    // $robots is null due to cache expiration or data do not exist
    // Make the database call and populate the variable
    $robots = Robots::find(array("order" => "id"));

    // Store it in the cache
    $cache->save($cacheKey, $robots);
}

// Use $robots :)
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}
```

Methods

public __construct ([*unknown* \$frontendOptions])

Phalcon\Cache\Frontend\Data constructor

public *integer* getLifetime ()

Returns the cache lifetime

public *boolean* isBuffering ()

Check whether if frontend is buffering output

public **start** ()

Starts output frontend. Actually, does nothing

public *string* getContent ()

Returns output cached content

public `stop()`
 Stops output frontend

public `string beforeStore (unknown $data)`
 Serializes data before storing them

public `mixed afterRetrieve (unknown $data)`
 Unserializes data after retrieval

2.58.42 Class Phalcon\Cache\Frontend\Json

implements Phalcon\Cache\FrontendInterface

Allows to cache data converting/deconverting them to JSON. This adapter uses the json_encode/json_decode PHP's functions As the data is encoded in JSON other systems accessing the same backend could process them

```
<?php

<?php

// Cache the data for 2 days
$frontCache = new \Phalcon\Cache\Frontend\Json(array(
    "lifetime" => 172800
));

//Create the Cache setting memcached connection options
$cache = new \Phalcon\Cache\Backend\Memcache($frontCache, array(
    'host' => 'localhost',
    'port' => 11211,
    'persistent' => false
));

//Cache arbitrary data
$cache->save('my-data', array(1, 2, 3, 4, 5));

//Get data
$data = $cache->get('my-data');
```

Methods

public `__construct ([unknown $frontendOptions])`
 Phalcon\Cache\Frontend\Base64 constructor

public `integer getLifetime ()`

Returns the cache lifetime

public `boolean isBuffering ()`

Check whether if frontend is buffering output

public `start ()`

Starts output frontend. Actually, does nothing

public `string getContent ()`

Returns output cached content

public **stop** ()

Stops output frontend

public *string* **beforeStore** (*unknown* \$data)

Serializes data before storing them

public *mixed* **afterRetrieve** (*unknown* \$data)

Unserializes data after retrieval

2.58.43 Class Phalcon\Cache\Frontend\None

implements Phalcon\Cache\FrontendInterface

Discards any kind of frontend data input. This frontend does not have expiration time or any other options

```
<?php

<?php

//Create a None Cache
$frontCache = new \Phalcon\Cache\Frontend\None();

// Create the component that will cache "Data" to a "Memcached" backend
// Memcached connection settings
$cache = new \Phalcon\Cache\Backend\Memcache($frontCache, array(
    "host" => "localhost",
    "port" => "11211"
));

// This Frontend always return the data as it's returned by the backend
$cakeKey = 'robots_order_id.cache';
$robots = $cache->get($cakeKey);
if ($robots === null) {

    // This cache doesn't perform any expiration checking, so the data is always expired
    // Make the database call and populate the variable
    $robots = Robots::find(array("order" => "id"));

    $cache->save($cakeKey, $robots);
}

// Use $robots :
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}
```

Methods

public *int* **getLifetime** ()

Returns cache lifetime, always one second expiring content

public *boolean* **isBuffering** ()

Check whether if frontend is buffering output, always false

public **start** ()

Starts output frontend

`public string getContent ()`

Returns output cached content

`public stop ()`

Stops output frontend

`public beforeStore (mixed $data)`

Prepare data to be stored

`public afterRetrieve (mixed $data)`

Prepares data to be retrieved to user

2.58.44 Class Phalcon\Cache\Frontend\Output

implements Phalcon\Cache\FrontendInterface

Allows to cache output fragments captured with ob_* functions

```
<?php

<?php

//Create an Output frontend. Cache the files for 2 days
$frontCache = new \Phalcon\Cache\Frontend\Output(array(
    "lifetime" => 172800
));

// Create the component that will cache from the "Output" to a "File" backend
// Set the cache file directory - it's important to keep the "/" at the end of
// the value for the folder
$cache = new \Phalcon\Cache\Backend\File($frontCache, array(
    "cacheDir" => "../app/cache/"
));

// Get/Set the cache file to ../app/cache/my-cache.html
$content = $cache->start("my-cache.html");

// If $content is null then the content will be generated for the cache
if ($content === null) {

    //Print date and time
    echo date("r");

    //Generate a link to the sign-up action
    echo Phalcon\Tag::linkTo(
        array(
            "user/signup",
            "Sign Up",
            "class" => "signup-button"
        )
    );

    // Store the output into the cache file
    $cache->save();
}
```

```
    } else {  
  
    // Echo the cached output  
    echo $content;  
}
```

Methods

public __construct ([*unknown* \$frontendOptions])

Phalcon\Cache\Frontend\Output constructor

public integer getLifetime ()

Returns the cache lifetime

public boolean isBuffering ()

Check whether if frontend is buffering output

public start ()

Starts output frontend. Currently, does nothing

public string getContent ()

Returns output cached content

public stop ()

Stops output frontend

public string beforeStore (*unknown* \$data)

Serializes data before storing them

public mixed afterRetrieve (*unknown* \$data)

Unserializes data after retrieval

2.58.45 Class Phalcon\Cache\Multiple

Allows to read to chained backends writing to multiple backends

```
<?php  
  
use Phalcon\Cache\Frontend\Data as DataFrontend,  
Phalcon\Cache\Multiple,  
Phalcon\Cache\Backend\Apc as ApcCache,  
Phalcon\Cache\Backend\Memcache as MemcacheCache,  
Phalcon\Cache\Backend\File as FileCache;  
  
$ultraFastFrontend = new DataFrontend(array(  
    "lifetime" => 3600  
));  
  
$fastFrontend = new DataFrontend(array(  
    "lifetime" => 86400  
));  
  
$slowFrontend = new DataFrontend(array(  
    "lifetime" => 604800  
));  
  
$multiple = new Multiple(array(  
    "backends" => array(  
        $ultraFastFrontend,  
        $fastFrontend,  
        $slowFrontend  
    )  
));  
  
$multiple->get("test");  
  
$multiple->set("test", "Hello World!", 3600);  
  
$multiple->get("test");  
  
$multiple->clear();
```

```

    "lifetime" => 604800
));

//Backends are registered from the fastest to the slower
$cache = new Multiple(array(
    new ApcCache($ultraFastFrontend, array(
        "prefix" => 'cache',
    )),
    new MemcacheCache($fastFrontend, array(
        "prefix" => 'cache',
        "host" => "localhost",
        "port" => "11211"
    )),
    new FileCache($slowFrontend, array(
        "prefix" => 'cache',
        "cacheDir" => "../app/cache/"
    ))
));
;

//Save, saves in every backend
$cache->save('my-key', $data);

```

Methods

public __construct ([*unknown* \$backends])

Phalcon\Cache\Multiple constructor

public Phalcon\Cache\Multiple push (*unknown* \$backend)

Adds a backend

public mixed get (*unknown* \$keyName, [*unknown* \$lifetime])

Returns a cached content reading the internal backends

public start (*unknown* \$keyName, [*unknown* \$lifetime])

Starts every backend

public save (*unknown* \$keyName, [*unknown* \$content], [*unknown* \$lifetime], [*unknown* \$stopBuffer])

Stores cached content into all backends and stops the frontend

public boolean delete (*unknown* \$keyName)

Deletes a value from each backend

public boolean exists (*unknown* \$keyName, [*unknown* \$lifetime])

Checks if cache exists in at least one backend

2.58.46 Class Phalcon\Cli\Router\Route

This class represents every route added to the router

Constants

string DEFAULT_DELIMITER

Methods

public **__construct** (*unknown* \$pattern, [*unknown* \$paths])

Phalcon\Cli\Router\Route constructor

public **string compilePattern** (*unknown* \$pattern)

Replaces placeholders from pattern returning a valid PCRE regular expression

public *array|boolean* **extractNamedParams** (*unknown* \$pattern)

Extracts parameters from a string

public **reConfigure** (*unknown* \$pattern, [*unknown* \$paths])

Reconfigure the route adding a new pattern and a set of paths

public **string getName** ()

Returns the route's name

public [Phalcon\Cli\Router\Route](#) **setName** (*unknown* \$name)

Sets the route's name

```
<?php
```

```
$router->add('/about', array(
    'controller' => 'about'
))->setName('about');
```

public [Phalcon\Cli\Router\Route](#) **beforeMatch** (*unknown* \$callback)

Sets a callback that is called if the route is matched. The developer can implement any arbitrary conditions here If the callback returns false the route is treated as not matched

public *mixed* **getBeforeMatch** ()

Returns the 'before match' callback if any

public **string getRouteId** ()

Returns the route's id

public **string getPattern** ()

Returns the route's pattern

public **string getCompiledPattern** ()

Returns the route's compiled pattern

public *array* **getPaths** ()

Returns the paths

public *array* **getReversedPaths** ()

Returns the paths using positions as keys and names as values

public [Phalcon\Cli\Router\Route](#) **convert** (*unknown* \$name, *unknown* \$converter)

Adds a converter to perform an additional transformation for certain parameter

public *array* **getConverters** ()

Returns the router converter

```
public static reset ()
Resets the internal route id generator
public static delimiter ([unknown $delimiter])
Set the routing delimiter
public static string getDelimiter ()
Get routing delimiter
```

2.58.47 Class Phalcon\Config

implements ArrayAccess, Countable

Phalcon\Config is designed to simplify the access to, and the use of, configuration data within applications. It provides a nested object property based user interface for accessing this configuration data within application code.

```
<?php

$config = new \Phalcon\Config(array(
    "database" => array(
        "adapter" => "Mysql",
        "host" => "localhost",
        "username" => "scott",
        "password" => "cheetah",
        "dbname" => "test_db"
    ),
    "phalcon" => array(
        "controllersDir" => "../app/controllers/",
        "modelsDir" => "../app/models/",
        "viewsDir" => "../app/views/"
    )
));
```

Methods

public **__construct** ([*unknown* \$arrayConfig])

Phalcon\Config constructor

public **offsetExists** (*unknown* \$index)

Allows to check whether an attribute is defined using the array-syntax

```
<?php

var_dump(isset($config['database']));
```

public **get** (*unknown* \$index, [*unknown* \$defaultValue])

Gets an attribute from the configuration, if the attribute isn't defined returns null If the value is exactly null or is not defined the default value will be used instead

```
<?php

echo $config->get('controllersDir', '../app/controllers/');
```

public **offsetGet** (*unknown \$index*)

Gets an attribute using the array-syntax

```
<?php  
print_r($config['database']);
```

public **offsetSet** (*unknown \$index, unknown \$value*)

Sets an attribute using the array-syntax

```
<?php  
$config['database'] = array('type' => 'Sqlite');
```

public **offsetUnset** (*unknown \$index*)

Unsets an attribute using the array-syntax

```
<?php  
unset($config['database']);
```

public *this merged config* **merge** (*unknown \$config*)

Merges a configuration into the current one

```
<?php  
$appConfig = new \Phalcon\Config(array('database' => array('host' => 'localhost')));  
$globalConfig->merge($config2);
```

public **toArray** ()

Converts recursively the object to an array

```
<?php  
print_r($config->toArray());
```

public **count** ()

Returns the count of properties set in the config

```
<?php  
print count($config);
```

or

```
<?php  
print $config->count();
```

public static **__set_state** (*unknown \$data*)

Restores the state of a Phalcon\Config object

private *Config merged config* **_merge** (*unknown \$config, [unknown \$instance]*)

Helper method for merge configs (forwarding nested config instance)

2.58.48 Class Phalcon\Config\Adapter\Ini

extends class Phalcon\Config

implements Countable, ArrayAccess

Reads ini files and converts them to Phalcon\Config objects. Given the next configuration file:

```
<?php

[database]
adapter = Mysql
host = localhost
username = scott
password = cheetah
dbname = test_db

[phalcon]
controllersDir = ".../app/controllers/"
modelsDir = ".../app/models/"
viewsDir = ".../app/views/"

You can read it as follows:
```

```
<?php

$config = new Phalcon\Config\Adapter\Ini("path/config.ini");
echo $config->phalcon->controllersDir;
echo $config->database->username;
```

Methods

public __construct (*unknown* \$filePath)

Phalcon\Config\Adapter\Ini constructor

protected array parsed path _parseIniString (*unknown* \$path, *unknown* \$value)

Build multidimensional array from string

```
<?php

$this->_parseIniString('path.hello.world', 'value for last key');

// result
[
    'path' => [
        'hello' => [
            'world' => 'value for last key',
        ],
    ],
];
```

public offsetExists (*unknown* \$index) inherited from Phalcon\Config

Allows to check whether an attribute is defined using the array-syntax

```
<?php

var_dump(isset($config['database']));
```

public **get** (*unknown* \$index, [*unknown* \$defaultValue]) inherited from Phalcon\Config

Gets an attribute from the configuration, if the attribute isn't defined returns null If the value is exactly null or is not defined the default value will be used instead

```
<?php  
  
echo $config->get('controllersDir', '../app/controllers/');
```

public **offsetGet** (*unknown* \$index) inherited from Phalcon\Config

Gets an attribute using the array-syntax

```
<?php  
  
print_r($config['database']);
```

public **offsetSet** (*unknown* \$index, *unknown* \$value) inherited from Phalcon\Config

Sets an attribute using the array-syntax

```
<?php  
  
$config['database'] = array('type' => 'Sqlite');
```

public **offsetUnset** (*unknown* \$index) inherited from Phalcon\Config

Unsets an attribute using the array-syntax

```
<?php  
  
unset($config['database']);
```

public *this merged config* **merge** (*unknown* \$config) inherited from Phalcon\Config

Merges a configuration into the current one

```
<?php  
  
$appConfig = new \Phalcon\Config(array('database' => array('host' => 'localhost')));  
$globalConfig->merge($config2);
```

public **toArray** () inherited from Phalcon\Config

Converts recursively the object to an array

```
<?php  
  
print_r($config->toArray());
```

public **count** () inherited from Phalcon\Config

Returns the count of properties set in the config

```
<?php  
  
print count($config);
```

or

```
<?php  
  
print $config->count();
```

public static **__set_state** (*unknown \$data*) inherited from Phalcon\Config

Restores the state of a Phalcon\Config object

private *Config merged config* **_merge** (*unknown \$config, [unknown \$instance]*) inherited from Phalcon\Config

Helper method for merge configs (forwarding nested config instance)

2.58.49 Class Phalcon\Config\Adapter\Json

extends class Phalcon\Config

implements Countable, ArrayAccess

Reads JSON files and converts them to Phalcon\Config objects. Given the following configuration file:

```
<?php
{
    "phalcon": {
        "baseuri": "\/phalcon",
        "models": {
            "metadata": "memory"
        }
    }
}
```

You can read it **as** follows:

```
<?php
$config = new Phalcon\Config\Adapter\Json("path/config.json");
echo $config->phalcon->baseuri;
echo $config->models->metadata;
```

Methods

public **__construct** (*unknown \$filePath*)

Phalcon\Config\Adapter\Json constructor

public **offsetExists** (*unknown \$index*) inherited from Phalcon\Config

Allows to check whether an attribute is defined using the array-syntax

```
<?php
var_dump(isset($config['database']));
```

public **get** (*unknown \$index, [unknown \$defaultValue]*) inherited from Phalcon\Config

Gets an attribute from the configuration, if the attribute isn't defined returns null If the value is exactly null or is not defined the default value will be used instead

```
<?php
echo $config->get('controllersDir', '../app/controllers/');
```

public **offsetGet** (*unknown \$index*) inherited from Phalcon\Config

Gets an attribute using the array-syntax

```
<?php
print_r($config['database']);
```

public **offsetSet** (*unknown* \$index, *unknown* \$value) inherited from Phalcon\Config

Sets an attribute using the array-syntax

```
<?php  
$config['database'] = array('type' => 'Sqlite');
```

public **offsetUnset** (*unknown* \$index) inherited from Phalcon\Config

Unsets an attribute using the array-syntax

```
<?php  
unset($config['database']);
```

public *this merged config* **merge** (*unknown* \$config) inherited from Phalcon\Config

Merges a configuration into the current one

```
<?php  
$appConfig = new \Phalcon\Config(array('database' => array('host' => 'localhost')));  
$globalConfig->merge($config2);
```

public **toArray** () inherited from Phalcon\Config

Converts recursively the object to an array

```
<?php  
print_r($config->toArray());
```

public **count** () inherited from Phalcon\Config

Returns the count of properties set in the config

```
<?php  
print count($config);
```

or

```
<?php  
print $config->count();
```

public static **__set_state** (*unknown* \$data) inherited from Phalcon\Config

Restores the state of a Phalcon\Config object

private *Config merged config* **_merge** (*unknown* \$config, [*unknown* \$instance]) inherited from Phalcon\Config

Helper method for merge configs (forwarding nested config instance)

2.58.50 Class Phalcon\Config\Adapter\Php

extends class Phalcon\Config

implements Countable, ArrayAccess

Reads php files and converts them to Phalcon\Config objects. Given the next configuration file:

```
<?php

<?php
return array(
    'database' => array(
        'adapter' => 'Mysql',
        'host' => 'localhost',
        'username' => 'scott',
        'password' => 'cheetah',
        'dbname' => 'test_db'
    ),
    'phalcon' => array(
        'controllersDir' => '../app/controllers/',
        'modelsDir' => '../app/models/',
        'viewsDir' => '../app/views/'
    )
);
```

You can read it as follows:

```
<?php

$config = new Phalcon\Config\Adapter\Php("path/config.php");
echo $config->phalcon->controllersDir;
echo $config->database->username;
```

Methods

public __construct (*unknown* \$filePath)

Phalcon\Config\Adapter\Php constructor

public offsetExists (*unknown* \$index) inherited from Phalcon\Config

Allows to check whether an attribute is defined using the array-syntax

```
<?php

var_dump(isset($config['database']));
```

public get (*unknown* \$index, [*unknown* \$defaultValue]) inherited from Phalcon\Config

Gets an attribute from the configuration, if the attribute isn't defined returns null If the value is exactly null or is not defined the default value will be used instead

```
<?php

echo $config->get('controllersDir', '../app/controllers/');
```

public offsetGet (*unknown* \$index) inherited from Phalcon\Config

Gets an attribute using the array-syntax

```
<?php

print_r($config['database']);
```

public offsetSet (*unknown* \$index, *unknown* \$value) inherited from Phalcon\Config

Sets an attribute using the array-syntax

```
<?php  
$config['database'] = array('type' => 'Sqlite');
```

public **offsetUnset** (*unknown \$index*) inherited from Phalcon\Config

Unsets an attribute using the array-syntax

```
<?php  
unset ($config['database']);
```

public *this merged config merge* (*unknown \$config*) inherited from Phalcon\Config

Merges a configuration into the current one

```
<?php  
$appConfig = new \Phalcon\Config(array('database' => array('host' => 'localhost')));  
$globalConfig->merge($config2);
```

public **toArray** () inherited from Phalcon\Config

Converts recursively the object to an array

```
<?php  
print_r($config->toArray());
```

public **count** () inherited from Phalcon\Config

Returns the count of properties set in the config

```
<?php  
print count($config);
```

or

```
<?php  
print $config->count();
```

public static **__set_state** (*unknown \$data*) inherited from Phalcon\Config

Restores the state of a Phalcon\Config object

private *Config merged config _merge* (*unknown \$config, [unknown \$instance]*) inherited from Phalcon\Config

Helper method for merge configs (forwarding nested config instance)

2.58.51 Class Phalcon\Config\Adapter\Yaml

extends class Phalcon\Config

implements Countable, ArrayAccess

Reads YAML files and converts them to Phalcon\Config objects. Given the following configuration file:

```
<?php  
phalcon
```

```
baseuri: /phalcon/
models:
    metadata: memory
```

You can read it **as** follows:

```
<?php

$config = new Phalcon\Config\Adapter\Yaml("path/config.yaml");
echo $config->phalcon->baseuri;
echo $config->models->metadata;
```

Methods

public __construct (string \$filePath, [array \$callbacks])

Phalcon\Config\Adapter\Yaml constructor

public offsetExists (unknown \$index) inherited from Phalcon\Config

Allows to check whether an attribute is defined using the array-syntax

```
<?php

var_dump(isset($config['database']));
```

public get (unknown \$index, [unknown \$defaultValue]) inherited from Phalcon\Config

Gets an attribute from the configuration, if the attribute isn't defined returns null If the value is exactly null or is not defined the default value will be used instead

```
<?php

echo $config->get('controllersDir', '../app/controllers/');
```

public offsetGet (unknown \$index) inherited from Phalcon\Config

Gets an attribute using the array-syntax

```
<?php

print_r($config['database']);
```

public offsetSet (unknown \$index, unknown \$value) inherited from Phalcon\Config

Sets an attribute using the array-syntax

```
<?php

$config['database'] = array('type' => 'Sqlite');
```

public offsetUnset (unknown \$index) inherited from Phalcon\Config

Unsets an attribute using the array-syntax

```
<?php

unset($config['database']);
```

public this merged config merge (unknown \$config) inherited from Phalcon\Config

Merges a configuration into the current one

```
<?php  
  
$appConfig = new \Phalcon\Config(array('database' => array('host' => 'localhost')));  
$globalConfig->merge($config2);
```

public **toArray** () inherited from Phalcon\Config

Converts recursively the object to an array

```
<?php  
  
print_r($config->toArray());
```

public **count** () inherited from Phalcon\Config

Returns the count of properties set in the config

```
<?php  
  
print count($config);
```

or

```
<?php  
  
print $config->count();
```

public static **_set_state** (*unknown* \$data) inherited from Phalcon\Config

Restores the state of a Phalcon\Config object

private *Config merged config* **_merge** (*unknown* \$config, [*unknown* \$instance]) inherited from Phalcon\Config

Helper method for merge configs (forwarding nested config instance)

2.58.52 Class Phalcon\Config\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **_clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception
Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception
Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception
Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception
Gets the stack trace as a string

public *string* **__toString** () inherited from Exception
String representation of the exception

2.58.53 Class Phalcon\\Crypt

implements Phalcon\\CryptInterface

Provides encryption facilities to phalcon applications

```
<?php

$crypt = new \Phalcon\Crypt();

$key = 'le password';
$text = 'This is a secret text';

$encrypted = $crypt->encrypt($text, $key);

echo $crypt->decrypt($encrypted, $key);
```

Constants

integer **PADDING_DEFAULT**
integer **PADDING_ANSI_X_923**
integer **PADDING_PKCS7**
integer **PADDING_ISO_10126**
integer **PADDING_ISO_IEC_7816_4**
integer **PADDING_ZERO**
integer **PADDING_SPACE**

Methods

public Phalcon\\CryptInterface **setPadding** (*unknown* \$scheme)
public Phalcon\\Crypt **setCipher** (*unknown* \$cipher)
Sets the cipher algorithm
public *string* **getCipher** ()

Returns the current cipher

`public Phalcon\Crypt setMode (unknown $mode)`

Sets the encrypt/decrypt mode

`public string getMode ()`

Returns the current encryption mode

`public Phalcon\Crypt setKey (unknown $key)`

Sets the encryption key

`public string getKey ()`

Returns the encryption key

`private _cryptPadText (unknown $text, unknown $mode, unknown $blockSize, unknown $paddingType)`

`private _cryptUnpadText (unknown $text, unknown $mode, unknown $blockSize, unknown $paddingType)`

If the function detects that the text was not padded, it will return it unmodified

`public string encrypt (unknown $text, [unknown $key])`

Encrypts a text

```
<?php
```

```
$encrypted = $crypt->encrypt ("Ultra-secret text", "encrypt password");
```

`public string decrypt (unknown $text, [unknown $key])`

Decrypts an encrypted text

```
<?php
```

```
echo $crypt->decrypt ($encrypted, "decrypt password");
```

`public string encryptBase64 (unknown $text, [unknown $key], [unknown $safe])`

Encrypts a text returning the result as a base64 string

`public string decryptBase64 (unknown $text, [unknown $key], [unknown $safe])`

Decrypt a text that is coded as a base64 string

`public array getAvailableCiphers ()`

Returns a list of available cyphers

`public array getAvailableModes ()`

Returns a list of available modes

2.58.54 Class Phalcon\Crypt\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from *Exception*
Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from *Exception*
Exception constructor

final public *string* **getMessage** () inherited from *Exception*
Gets the *Exception* message

final public *int* **getCode** () inherited from *Exception*
Gets the *Exception* code

final public *string* **getFile** () inherited from *Exception*
Gets the file in which the exception occurred

final public *int* **getLine** () inherited from *Exception*
Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from *Exception*
Gets the stack trace

final public *Exception* **getPrevious** () inherited from *Exception*
Returns previous *Exception*

final public *Exception* **getTraceAsString** () inherited from *Exception*
Gets the stack trace as a string

public *string* **__toString** () inherited from *Exception*
String representation of the exception

2.58.55 Abstract class Phalcon\Db

Phalcon\Db and its related classes provide a simple SQL database interface for Phalcon Framework. The *Phalcon\Db* is the basic class you use to connect your PHP application to an RDBMS. There is a different adapter class for each brand of RDBMS. This component is intended to lower level database operations. If you want to interact with databases using higher level of abstraction use *Phalcon\ Mvc\ Model*. *Phalcon\Db* is an abstract class. You only can use it with a database adapter like *Phalcon\Db\ Adapter\Pdo*

```
<?php

try {

$connection = new \Phalcon\Db\Adapter\Pdo\Mysql (array (
    'host' => '192.168.0.11',
    'username' => 'sigma',
    'password' => 'secret',
    'dbname' => 'blog',
    'port' => '3306',
));

$result = $connection->query("SELECT * FROM robots LIMIT 5");
$result->setFetchMode(\Phalcon\Db::FETCH_NUM);
```

```
while ($robot = $result->fetch()) {
    print_r($robot);
}

} catch (Phalcon\Db\Exception $e) {
echo $e->getMessage(), PHP_EOL;
}
```

Constants

integer **FETCH_ASSOC**

integer **FETCH_BOTH**

integer **FETCH_NUM**

integer **FETCH_OBJ**

Methods

public static **setup** (*unknown* \$options)

Enables/disables options in the Database component

2.58.56 Abstract class Phalcon\Db\Adapter

implements [Phalcon\Events\EventsAwareInterface](#)

Base class for Phalcon\Db adapters

Methods

public **getDialectType** ()

Name of the dialect used

public **getType** ()

Type of database system the adapter is used for

public **getSqlVariables** ()

Active SQL bound parameter variables

public **__construct** (*unknown* \$descriptor)

Phalcon\Db\Adapter constructor

public **setEventsManager** (*unknown* \$eventsManager)

Sets the event manager

public [Phalcon\Events\ManagerInterface](#) **getEventsManager** ()

Returns the internal event manager

public **setDialect** (*unknown* \$dialect)

Sets the dialect used to produce the SQL

public Phalcon\Db\DialectInterface getDialect ()

Returns internal dialect instance

public array fetchOne (unknown \$sqlQuery, [unknown \$fetchMode], [unknown \$bindParams], [unknown \$bindTypes])

Returns the first row in a SQL query result

```
<?php

//Getting first robot
$robot = $connection->fetchOne("SELECT * FROM robots");
print_r($robot);

//Getting first robot with associative indexes only
$robot = $connection->fetchOne("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
print_r($robot);
```

public array fetchAll (unknown \$sqlQuery, [unknown \$fetchMode], [unknown \$bindParams], [unknown \$bindTypes])

Dumps the complete result of a query into an array

```
<?php

//Getting all robots with associative indexes only
$robots = $connection->fetchAll("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
foreach ($robots as $robot) {
    print_r($robot);
}

//Getting all robots that contains word "robot" withing the name
$robots = $connection->fetchAll("SELECT * FROM robots WHERE name LIKE :name",
    Phalcon\Db::FETCH_ASSOC,
    array('name' => '%robot%')
);
foreach($robots as $robot){
    print_r($robot);
}
```

public string| fetchColumn (unknown \$sqlQuery, [unknown \$placeholders], [unknown \$column])

Returns the n'th field of first row in a SQL query result

```
<?php

//Getting count of robots
$robotsCount = $connection->fetchColumn("SELECT count(*) FROM robots");
print_r($robotsCount);

//Getting name of last edited robot
$robot = $connection->fetchColumn("SELECT id, name FROM robots ORDER BY modified DESC");
print_r($robot);
```

public boolean insert (unknown \$table, unknown \$values, [unknown \$fields], [unknown \$dataTypes])

Inserts data into a table using custom RBDM SQL syntax

```
<?php

//Inserting a new robot
$success = $connection->insert(
```

```

"robots",
array("Astro Boy", 1952),
array("name", "year")
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);

```

public boolean insertAsDict (unknown \$table, unknown \$data, [unknown \$dataTypes])

Inserts data into a table using custom RBDM SQL syntax Another, more convenient syntax

```

<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array(
        "name" => "Astro Boy",
        "year" => 1952
    )
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);

```

public boolean update (unknown \$table, unknown \$fields, unknown \$values, [unknown \$whereCondition], [unknown \$dataTypes])

Updates data on a table using custom RBDM SQL syntax

```

<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101

//Updating existing robot with array condition and $dataTypes
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    array(
        'conditions' => "id = ?",
        'bind' => array($some_unsafe_id),
        'bindTypes' => array(PDO::PARAM_INT) //use only if you use $dataTypes param
    ),
    array(PDO::PARAM_STR)
);

```

Warning! If \$whereCondition is string it not escaped.

public boolean updateAsDict (unknown \$table, unknown \$data, [unknown \$whereCondition], [unknown \$dataTypes])

Updates data on a table using custom RBDM SQL syntax Another, more convenient syntax

```
<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array(
        "name" => "New Astro Boy"
    ),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101
```

`public boolean delete (unknown $table, [unknown $whereCondition], [unknown $placeholders], [unknown $dataTypes])`

Deletes data from a table using custom RBDM SQL syntax

```
<?php

//Deleting existing robot
$success = $connection->delete(
    "robots",
    "id = 101"
);

//Next SQL sentence is generated
DELETE FROM `robots` WHERE `id` = 101
```

`public string getColumnList (unknown $columnList)`

Gets a list of columns

`public string limit (unknown $sqlQuery, unknown $number)`

Appends a LIMIT clause to \$sqlQuery argument

```
<?php

echo $connection->limit ("SELECT * FROM robots", 5);
```

`public boolean tableExists (unknown $tableName, [unknown $schemaName])`

Generates SQL checking for the existence of a schema.table

```
<?php

var_dump ($connection->tableExists ("blog", "posts"));
```

`public boolean viewExists (unknown $viewName, [unknown $schemaName])`

Generates SQL checking for the existence of a schema.view

```
<?php

var_dump ($connection->viewExists ("active_users", "posts"));
```

`public string forUpdate (unknown $sqlQuery)`

Returns a SQL modified with a FOR UPDATE clause

public *string* **sharedLock** (*unknown* \$sqlQuery)

Returns a SQL modified with a LOCK IN SHARE MODE clause

public *boolean* **createTable** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$definition)

Creates a table

public *boolean* **dropTable** (*unknown* \$tableName, [*unknown* \$schemaName], [*unknown* \$IfExists])

Drops a table from a schema/database

public *boolean* **createView** (*unknown* \$viewName, *unknown* \$definition, [*unknown* \$schemaName])

Creates a view

public *boolean* **dropView** (*unknown* \$viewName, [*unknown* \$schemaName], [*unknown* \$IfExists])

Drops a view

public *boolean* **addColumn** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$column)

Adds a column to a table

public *boolean* **modifyColumn** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$column)

Modifies a table column based on a definition

public *boolean* **dropColumn** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$columnName)

Drops a column from a table

public *boolean* **addIndex** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$index)

Adds an index to a table

public *boolean* **dropIndex** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$indexName)

Drop an index from a table

public *boolean* **addPrimaryKey** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$index)

Adds a primary key to a table

public *boolean* **dropPrimaryKey** (*unknown* \$tableName, *unknown* \$schemaName)

Drops a table's primary key

public *boolean true* **addForeignKey** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$reference)

Adds a foreign key to a table

public *boolean true* **dropForeignKey** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$referenceName)

Drops a foreign key from a table

public *string* **getColumnDefinition** (*unknown* \$column)

Returns the SQL column definition from a column

public *array* **listTables** ([*unknown* \$schemaName])

List all tables on a database

```
<?php  
print_r($connection->listTables("blog"));
```

public array listViews ([*unknown* \$schemaName])

List all views on a database

```
<?php
print_r($connection->listViews ("blog"));
```

public Phalcon\Db\Index [] describeIndexes (*unknown* \$table, [*unknown* \$schema])

Lists table indexes

```
<?php
print_r($connection->describeIndexes ('robots_parts'));
```

public Phalcon\Db\Reference [] describeReferences (*unknown* \$table, [*unknown* \$schema])

Lists table references

```
<?php
print_r($connection->describeReferences ('robots_parts'));
```

public array tableOptions (*unknown* \$tableName, [*unknown* \$schemaName])

Gets creation options from a table

```
<?php
print_r($connection->tableOptions ('robots'));
```

public boolean createSavepoint (*unknown* \$name)

Creates a new savepoint

public boolean releaseSavepoint (*unknown* \$name)

Releases given savepoint

public boolean rollbackSavepoint (*unknown* \$name)

Rollbacks given savepoint

public Phalcon\Db\AdapterInterface setNestedTransactionsWithSavepoints (*unknown* \$nestedTransactionsWithSavepoints)

Set if nested transactions should use savepoints

public boolean isNestedTransactionsWithSavepoints ()

Returns if nested transactions should use savepoints

public string getNestedTransactionSavepointName ()

Returns the savepoint name to use for nested transactions

public Phalcon\Db\RawValue getDefaultIdValue ()

Returns the default identity value to be inserted in an identity column

```
<?php
//Inserting a new robot with a valid default value for the column 'id'
$success = $connection->insert (
    "robots",
```

```
array($connection->getDefaultIdValue(), "Astro Boy", 1952),
array("id", "name", "year")
);
```

public boolean supportSequences ()

Check whether the database system requires a sequence to produce auto-numeric values

public boolean useExplicitIdValue ()

Check whether the database system requires an explicit value for identity columns

public array getDescriptor ()

Return descriptor used to connect to the active database

public string getConnectionId ()

Gets the active connection unique identifier

public string getSQLStatement ()

Active SQL statement in the object

public string getRealSQLStatement ()

Active SQL statement in the object without replace bound parameters

public array getSQLBindTypes ()

Active SQL statement in the object

2.58.57 Abstract class Phalcon\Db\Adapter\Pdo

extends abstract class Phalcon\Db\Adapter

implements Phalcon\Events\EventsAwareInterface

Phalcon\Db\Adapter\Pdo is the Phalcon\Db that internally uses PDO to connect to a database

```
<?php

$connection = new \Phalcon\Db\Adapter\Pdo\Mysql(array(
    'host' => '192.168.0.11',
    'username' => 'sigma',
    'password' => 'secret',
    'dbname' => 'blog',
    'port' => '3306'
));
```

Methods

public __construct (unknown \$descriptor)

Constructor for Phalcon\Db\Adapter\Pdo

public boolean connect ([unknown \$descriptor])

This method is automatically called in Phalcon\Db\Adapter\Pdo constructor. Call it when you need to restore a database connection

```
<?php

//Make a connection
$connection = new \Phalcon\Db\Adapter\Pdo\Mysql(array(
    'host' => '192.168.0.11',
    'username' => 'sigma',
    'password' => 'secret',
    'dbname' => 'blog',
));

//Reconnect
$connection->connect();
```

public PDOStatement prepare (unknown \$sqlStatement)

Returns a PDO prepared statement to be executed with ‘executePrepared’

```
<?php

$statement = $db->prepare('SELECT * FROM robots WHERE name = :name');
$result = $connection->executePrepared($statement, array('name' => 'Voltron'));
```

public PDOStatement executePrepared (unknown \$statement, unknown \$placeholders, unknown \$dataTypes)

Executes a prepared statement binding. This function uses integer indexes starting from zero

```
<?php

$statement = $db->prepare('SELECT * FROM robots WHERE name = :name');
$result = $connection->executePrepared($statement, array('name' => 'Voltron'));
```

public Phalcon\Db\ResultInterface |bool query (unknown \$sqlStatement, [unknown \$bindParams], [unknown \$bindTypes])

Sends SQL statements to the database server returning the success state. Use this method only when the SQL statement sent to the server is returning rows

```
<?php

//Querying data
$resultset = $connection->query("SELECT * FROM robots WHERE type='mechanical'");
$resultset = $connection->query("SELECT * FROM robots WHERE type=?", array("mechanical"));
```

public boolean execute (unknown \$sqlStatement, [unknown \$bindParams], [unknown \$bindTypes])

Sends SQL statements to the database server returning the success state. Use this method only when the SQL statement sent to the server doesn’t return any row

```
<?php

//Inserting data
$success = $connection->execute("INSERT INTO robots VALUES (1, 'Astro Boy')");
$success = $connection->execute("INSERT INTO robots VALUES (?, ?)", array(1, 'Astro Boy'));
```

public int affectedRows ()

Returns the number of affected rows by the lastest INSERT/UPDATE/DELETE executed in the database system

```
<?php
```

```
$connection->execute("DELETE FROM robots");
echo $connection->affectedRows(), ' were deleted';
```

public boolean close ()

Closes the active connection returning success. Phalcon automatically closes and destroys active connections when the request ends

public string escapeIdentifier (*unknown* \$identifier)

Escapes a column/table/schema name

```
<?php

$escapedTable = $connection->escapeIdentifier('robots');
$escapedTable = $connection->escapeIdentifier(array('store', 'robots'));
```

public string escapeString (*unknown* \$str)

Escapes a value to avoid SQL injections according to the active charset in the connection

```
<?php

$escapedStr = $connection->escapeString('some dangerous value');
```

public array convertBoundParams (*string* \$sql, [*array* \$params])

Converts bound parameters such as :name: or ?1 into PDO bind params ?

```
<?php

print_r($connection->convertBoundParams('SELECT * FROM robots WHERE name = :name:', array('Bender')));
```

public int|boolean lastInsertId ([*unknown* \$sequenceName])

Returns the insert id for the auto_increment/serial column inserted in the lastest executed SQL statement

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array("Astro Boy", 1952),
    array("name", "year")
);

//Getting the generated id
$id = $connection->lastInsertId();
```

public boolean begin ([*unknown* \$nesting])

Starts a transaction in the connection

public boolean rollback ([*unknown* \$nesting])

Rollbacks the active transaction in the connection

public boolean commit ([*unknown* \$nesting])

Commits the active transaction in the connection

public int getTransactionLevel ()

Returns the current transaction nesting level

public boolean isUnderTransaction ()

Checks whether the connection is under a transaction

```
<?php
$connection->begin();
var_dump($connection->isUnderTransaction()); //true
```

public PDO getInternalHandler ()

Return internal PDO handler

public array getErrorInfo ()

Return the error info, if any

public getDialectType () inherited from Phalcon\Db\Adapter

Name of the dialect used

public getType () inherited from Phalcon\Db\Adapter

Type of database system the adapter is used for

public getSqlVariables () inherited from Phalcon\Db\Adapter

Active SQL bound parameter variables

public setEventsManager (unknown \$eventsManager) inherited from Phalcon\Db\Adapter

Sets the event manager

public Phalcon\Events\ManagerInterface getEventsManager () inherited from Phalcon\Db\Adapter

Returns the internal event manager

public setDialect (unknown \$dialect) inherited from Phalcon\Db\Adapter

Sets the dialect used to produce the SQL

public Phalcon\Db\DialectInterface getDialect () inherited from Phalcon\Db\Adapter

Returns internal dialect instance

public array fetchOne (unknown \$sqlQuery, [unknown \$fetchMode], [unknown \$bindParams], [unknown \$bindTypes]) inherited from Phalcon\Db\Adapter

Returns the first row in a SQL query result

```
<?php
//Getting first robot
$robot = $connection->fetchOne("SELECT * FROM robots");
print_r($robot);

//Getting first robot with associative indexes only
$robot = $connection->fetchOne("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
print_r($robot);
```

public array fetchAll (unknown \$sqlQuery, [unknown \$fetchMode], [unknown \$bindParams], [unknown \$bindTypes]) inherited from Phalcon\Db\Adapter

Dumps the complete result of a query into an array

```
<?php

//Getting all robots with associative indexes only
$robots = $connection->fetchAll("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
foreach ($robots as $robot) {
    print_r($robot);
}

//Getting all robots that contains word "robot" withing the name
$robots = $connection->fetchAll("SELECT * FROM robots WHERE name LIKE :name",
    Phalcon\Db::FETCH_ASSOC,
    array('name' => '%robot%')
);
foreach($robots as $robot){
    print_r($robot);
}
```

public *string* **fetchColumn** (*unknown* \$sqlQuery, [*unknown* \$placeholders], [*unknown* \$column]) inherited from Phalcon\Db\Adapter

Returns the n'th field of first row in a SQL query result

```
<?php

//Getting count of robots
$robotsCount = $connection->fetchColumn("SELECT count(*) FROM robots");
print_r($robotsCount);

//Getting name of last edited robot
$robot = $connection->fetchColumn("SELECT id, name FROM robots ORDER BY modified DESC");
print_r($robot);
```

public *boolean* **insert** (*unknown* \$table, *unknown* \$values, [*unknown* \$fields], [*unknown* \$dataTypes]) inherited from Phalcon\Db\Adapter

Inserts data into a table using custom RBDM SQL syntax

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array("Astro Boy", 1952),
    array("name", "year")
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);
```

public *boolean* **insertAsDict** (*unknown* \$table, *unknown* \$data, [*unknown* \$dataTypes]) inherited from Phalcon\Db\Adapter

Inserts data into a table using custom RBDM SQL syntax Another, more convenient syntax

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array(
```

```

        "name" => "Astro Boy",
        "year" => 1952
    )
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);

```

public boolean update (unknown \$table, unknown \$fields, unknown \$values, [unknown \$whereCondition], [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Updates data on a table using custom RBDM SQL syntax

```

<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101

//Updating existing robot with array condition and $dataTypes
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    array(
        'conditions' => "id = ?",
        'bind' => array($some_unsafe_id),
        'bindTypes' => array(PDO::PARAM_INT) //use only if you use $dataTypes param
    ),
    array(PDO::PARAM_STR)
);

```

Warning! If \$whereCondition is string it not escaped.

public boolean updateAsDict (unknown \$table, unknown \$data, [unknown \$whereCondition], [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Updates data on a table using custom RBDM SQL syntax Another, more convenient syntax

```

<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array(
        "name" => "New Astro Boy"
    ),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101

```

public *boolean* **delete** (*unknown* \$table, [*unknown* \$whereCondition], [*unknown* \$placeholders], [*unknown* \$dataTypes]) inherited from Phalcon\Db\Adapter

Deletes data from a table using custom RBDM SQL syntax

```
<?php

//Deleting existing robot
$success = $connection->delete(
    "robots",
    "id = 101"
);

//Next SQL sentence is generated
DELETE FROM `robots` WHERE `id` = 101
```

public *string* **getColumnList** (*unknown* \$columnList) inherited from Phalcon\Db\Adapter

Gets a list of columns

public *string* **limit** (*unknown* \$sqlQuery, *unknown* \$number) inherited from Phalcon\Db\Adapter

Appends a LIMIT clause to \$sqlQuery argument

```
<?php

echo $connection->limit ("SELECT * FROM robots", 5);
```

public *boolean* **tableExists** (*unknown* \$tableName, [*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

Generates SQL checking for the existence of a schema.table

```
<?php

var_dump ($connection->tableExists("blog", "posts"));
```

public *boolean* **viewExists** (*unknown* \$viewName, [*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

Generates SQL checking for the existence of a schema.view

```
<?php

var_dump ($connection->viewExists("active_users", "posts"));
```

public *string* **forUpdate** (*unknown* \$sqlQuery) inherited from Phalcon\Db\Adapter

Returns a SQL modified with a FOR UPDATE clause

public *string* **sharedLock** (*unknown* \$sqlQuery) inherited from Phalcon\Db\Adapter

Returns a SQL modified with a LOCK IN SHARE MODE clause

public *boolean* **createTable** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$definition) inherited from Phalcon\Db\Adapter

Creates a table

public *boolean* **dropTable** (*unknown* \$tableName, [*unknown* \$schemaName], [*unknown* \$IfExists]) inherited from Phalcon\Db\Adapter

Drops a table from a schema/database

public *boolean* **createView** (*unknown* \$viewName, *unknown* \$definition, [*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

Creates a view

`public boolean dropView (unknown $viewName, [unknown $schemaName], [unknown $IfExists])` inherited from Phalcon\Db\Adapter

Drops a view

`public boolean addColumn (unknown $tableName, unknown $schemaName, unknown $column)` inherited from Phalcon\Db\Adapter

Adds a column to a table

`public boolean modifyColumn (unknown $tableName, unknown $schemaName, unknown $column)` inherited from Phalcon\Db\Adapter

Modifies a table column based on a definition

`public boolean dropColumn (unknown $tableName, unknown $schemaName, unknown $columnName)` inherited from Phalcon\Db\Adapter

Drops a column from a table

`public boolean addIndex (unknown $tableName, unknown $schemaName, unknown $index)` inherited from Phalcon\Db\Adapter

Adds an index to a table

`public boolean dropIndex (unknown $tableName, unknown $schemaName, unknown $indexName)` inherited from Phalcon\Db\Adapter

Drop an index from a table

`public boolean addPrimaryKey (unknown $tableName, unknown $schemaName, unknown $index)` inherited from Phalcon\Db\Adapter

Adds a primary key to a table

`public boolean dropPrimaryKey (unknown $tableName, unknown $schemaName)` inherited from Phalcon\Db\Adapter

Drops a table's primary key

`public boolean true addForeignKey (unknown $tableName, unknown $schemaName, unknown $reference)` inherited from Phalcon\Db\Adapter

Adds a foreign key to a table

`public boolean true dropForeignKey (unknown $tableName, unknown $schemaName, unknown $referenceName)` inherited from Phalcon\Db\Adapter

Drops a foreign key from a table

`public string getColumnDefinition (unknown $column)` inherited from Phalcon\Db\Adapter

Returns the SQL column definition from a column

`public array listTables ([unknown $schemaName])` inherited from Phalcon\Db\Adapter

List all tables on a database

```
<?php
    print_r($connection->listTables("blog"));

```

`public array listViews ([unknown $schemaName])` inherited from Phalcon\Db\Adapter

List all views on a database

```
<?php  
print_r($connection->listViews("blog"));
```

public **Phalcon\Db\Index** [] **describeIndexes** (*unknown \$table*, [*unknown \$schema*]) inherited from Phalcon\Db\Adapter

Lists table indexes

```
<?php  
print_r($connection->describeIndexes('robots_parts'));
```

public **Phalcon\Db\Reference** [] **describeReferences** (*unknown \$table*, [*unknown \$schema*]) inherited from Phalcon\Db\Adapter

Lists table references

```
<?php  
print_r($connection->describeReferences('robots_parts'));
```

public *array* **tableOptions** (*unknown \$tableName*, [*unknown \$schemaName*]) inherited from Phalcon\Db\Adapter

Gets creation options from a table

```
<?php  
print_r($connection->tableOptions('robots'));
```

public *boolean* **createSavepoint** (*unknown \$name*) inherited from Phalcon\Db\Adapter

Creates a new savepoint

public *boolean* **releaseSavepoint** (*unknown \$name*) inherited from Phalcon\Db\Adapter

Releases given savepoint

public *boolean* **rollbackSavepoint** (*unknown \$name*) inherited from Phalcon\Db\Adapter

Rollbacks given savepoint

public **Phalcon\Db\AdapterInterface** **setNestedTransactionsWithSavepoints** (*unknown \$nestedTransactionsWithSavepoints*) inherited from Phalcon\Db\Adapter

Set if nested transactions should use savepoints

public *boolean* **isNestedTransactionsWithSavepoints** () inherited from Phalcon\Db\Adapter

Returns if nested transactions should use savepoints

public *string* **getNestedTransactionSavepointName** () inherited from Phalcon\Db\Adapter

Returns the savepoint name to use for nested transactions

public **Phalcon\Db\RawValue** **getDefaultIdValue** () inherited from Phalcon\Db\Adapter

Returns the default identity value to be inserted in an identity column

```
<?php  
  
//Inserting a new robot with a valid default value for the column 'id'  
$success = $connection->insert(  
    "robots",  
    array($connection->getDefaultIdValue(), "Astro Boy", 1952),
```

```
    array("id", "name", "year")
);
```

public boolean supportSequences () inherited from Phalcon\Db\Adapter

Check whether the database system requires a sequence to produce auto-numeric values

public boolean useExplicitIdValue () inherited from Phalcon\Db\Adapter

Check whether the database system requires an explicit value for identity columns

public array getDescriptor () inherited from Phalcon\Db\Adapter

Return descriptor used to connect to the active database

public string getConnectionId () inherited from Phalcon\Db\Adapter

Gets the active connection unique identifier

public string getSQLStatement () inherited from Phalcon\Db\Adapter

Active SQL statement in the object

public string getRealSQLStatement () inherited from Phalcon\Db\Adapter

Active SQL statement in the object without replace bound parameters

public array getSQLBindTypes () inherited from Phalcon\Db\Adapter

Active SQL statement in the object

2.58.58 Class Phalcon\Db\Adapter\Pdo\Mysql

extends abstract class Phalcon\Db\Adapter\Pdo

implements Phalcon\Events\EventsAwareInterface, Phalcon\Db\AdapterInterface

Specific functions for the Mysql database system

```
<?php

$config = array(
    "host" => "192.168.0.11",
    "dbname" => "blog",
    "port" => 3306,
    "username" => "sigma",
    "password" => "secret"
);

$connection = new \Phalcon\Db\Adapter\Pdo\Mysql($config);
```

Methods

public string escapeIdentifier (*unknown* \$identifier)

Escapes a column/table/schema name

public Phalcon\Db\Column [] describeColumns (*unknown* \$table, [*unknown* \$schema])

Returns an array of Phalcon\Db\Column objects describing a table

```
<?php  
print_r($connection->describeColumns ("posts"));
```

public **__construct** (*unknown* \$descriptor) inherited from Phalcon\Db\Adapter\Pdo

Constructor for Phalcon\Db\Adapter\Pdo

public **boolean connect** ([*unknown* \$descriptor]) inherited from Phalcon\Db\Adapter\Pdo

This method is automatically called in Phalcon\Db\Adapter\Pdo constructor. Call it when you need to restore a database connection

```
<?php  
  
//Make a connection  
$connection = new \Phalcon\Db\Adapter\Pdo\Mysql(array(  
    'host' => '192.168.0.11',  
    'username' => 'sigma',  
    'password' => 'secret',  
    'dbname' => 'blog',  
));  
  
//Reconnect  
$connection->connect();
```

public **PDOStatement prepare** (*unknown* \$sqlStatement) inherited from Phalcon\Db\Adapter\Pdo

Returns a PDO prepared statement to be executed with ‘executePrepared’

```
<?php  
  
$statement = $db->prepare('SELECT * FROM robots WHERE name = :name');  
$result = $connection->executePrepared($statement, array('name' => 'Voltron'));
```

public **PDOStatement executePrepared** (*unknown* \$statement, *unknown* \$placeholders, *unknown* \$dataTypes) inherited from Phalcon\Db\Adapter\Pdo

Executes a prepared statement binding. This function uses integer indexes starting from zero

```
<?php  
  
$statement = $db->prepare('SELECT * FROM robots WHERE name = :name');  
$result = $connection->executePrepared($statement, array('name' => 'Voltron'));
```

public **Phalcon\Db\ResultInterface |bool query** (*unknown* \$sqlStatement, [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter\Pdo

Sends SQL statements to the database server returning the success state. Use this method only when the SQL statement sent to the server is returning rows

```
<?php  
  
//Querying data  
$resultset = $connection->query("SELECT * FROM robots WHERE type='mechanical'");  
$resultset = $connection->query("SELECT * FROM robots WHERE type=?", array("mechanical"));
```

public **boolean execute** (*unknown* \$sqlStatement, [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter\Pdo

Sends SQL statements to the database server returning the success state. Use this method only when the SQL statement sent to the server doesn’t return any row

```
<?php

//Inserting data
$success = $connection->execute("INSERT INTO robots VALUES (1, 'Astro Boy')");
$success = $connection->execute("INSERT INTO robots VALUES (?, ?)", array(1, 'Astro Boy'));
```

public int affectedRows () inherited from Phalcon\Db\Adapter\Pdo

Returns the number of affected rows by the lastest INSERT/UPDATE/DELETE executed in the database system

```
<?php

$connection->execute("DELETE FROM robots");
echo $connection->affectedRows(), ' were deleted';
```

public boolean close () inherited from Phalcon\Db\Adapter\Pdo

Closes the active connection returning success. Phalcon automatically closes and destroys active connections when the request ends

public string escapeString (unknown \$str) inherited from Phalcon\Db\Adapter\Pdo

Escapes a value to avoid SQL injections according to the active charset in the connection

```
<?php

$escapedStr = $connection->escapeString('some dangerous value');
```

public array convertBoundParams (string \$sql, [array \$params]) inherited from Phalcon\Db\Adapter\Pdo

Converts bound parameters such as :name: or ?1 into PDO bind params ?

```
<?php

print_r($connection->convertBoundParams('SELECT * FROM robots WHERE name = :name:', array('Bender')));
```

public int|boolean lastInsertId ([unknown \$sequenceName]) inherited from Phalcon\Db\Adapter\Pdo

Returns the insert id for the auto_increment/serial column inserted in the lastest executed SQL statement

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array("Astro Boy", 1952),
    array("name", "year")
);

//Getting the generated id
$id = $connection->lastInsertId();
```

public boolean begin ([unknown \$nesting]) inherited from Phalcon\Db\Adapter\Pdo

Starts a transaction in the connection

public boolean rollback ([unknown \$nesting]) inherited from Phalcon\Db\Adapter\Pdo

Rollbacks the active transaction in the connection

public boolean commit ([unknown \$nesting]) inherited from Phalcon\Db\Adapter\Pdo

Commits the active transaction in the connection

public *int* **getTransactionLevel** () inherited from Phalcon\Db\Adapter\Pdo

Returns the current transaction nesting level

public *boolean* **isUnderTransaction** () inherited from Phalcon\Db\Adapter\Pdo

Checks whether the connection is under a transaction

```
<?php  
  
$connection->begin();  
var_dump($connection->isUnderTransaction()); //true
```

public *PDO* **getInternalHandler** () inherited from Phalcon\Db\Adapter\Pdo

Return internal PDO handler

public *array* **getErrorMessage** () inherited from Phalcon\Db\Adapter\Pdo

Return the error info, if any

public **getDialectType** () inherited from Phalcon\Db\Adapter

Name of the dialect used

public **getType** () inherited from Phalcon\Db\Adapter

Type of database system the adapter is used for

public **getSqlVariables** () inherited from Phalcon\Db\Adapter

Active SQL bound parameter variables

public **setEventsManager** (*unknown* \$eventsManager) inherited from Phalcon\Db\Adapter

Sets the event manager

public Phalcon\Events\ManagerInterface **getEventsManager** () inherited from Phalcon\Db\Adapter

Returns the internal event manager

public **setDialect** (*unknown* \$dialect) inherited from Phalcon\Db\Adapter

Sets the dialect used to produce the SQL

public Phalcon\Db\DialectInterface **getDialect** () inherited from Phalcon\Db\Adapter

Returns internal dialect instance

public *array* **fetchOne** (*unknown* \$sqlQuery, [*unknown* \$fetchMode], [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter

Returns the first row in a SQL query result

```
<?php  
  
//Getting first robot  
$robot = $connection->fetchOne("SELECT * FROM robots");  
print_r($robot);  
  
//Getting first robot with associative indexes only  
$robot = $connection->fetchOne("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);  
print_r($robot);
```

public *array* **fetchAll** (*unknown* \$sqlQuery, [*unknown* \$fetchMode], [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter

Dumps the complete result of a query into an array

```
<?php

//Getting all robots with associative indexes only
$robots = $connection->fetchAll("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
foreach ($robots as $robot) {
    print_r($robot);
}

//Getting all robots that contains word "robot" withing the name
$robots = $connection->fetchAll("SELECT * FROM robots WHERE name LIKE :name",
    Phalcon\Db::FETCH_ASSOC,
    array('name' => '%robot%')
);
foreach($robots as $robot){
    print_r($robot);
}
```

public *string* **fetchColumn** (*unknown* \$sqlQuery, [*unknown* \$placeholders], [*unknown* \$column]) inherited from Phalcon\Db\Adapter

Returns the n'th field of first row in a SQL query result

```
<?php

//Getting count of robots
$robotsCount = $connection->fetchColumn("SELECT count(*) FROM robots");
print_r($robotsCount);

//Getting name of last edited robot
$robot = $connection->fetchColumn("SELECT id, name FROM robots ORDER BY modified DESC");
print_r($robot);
```

public *boolean* **insert** (*unknown* \$table, *unknown* \$values, [*unknown* \$fields], [*unknown* \$dataTypes]) inherited from Phalcon\Db\Adapter

Inserts data into a table using custom RBDM SQL syntax

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array("Astro Boy", 1952),
    array("name", "year")
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);
```

public *boolean* **insertAsDict** (*unknown* \$table, *unknown* \$data, [*unknown* \$dataTypes]) inherited from Phalcon\Db\Adapter

Inserts data into a table using custom RBDM SQL syntax Another, more convenient syntax

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array(
```

```

        "name" => "Astro Boy",
        "year" => 1952
    )
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);

```

public boolean update (unknown \$table, unknown \$fields, unknown \$values, [unknown \$whereCondition], [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Updates data on a table using custom RBDM SQL syntax

```

<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101

//Updating existing robot with array condition and $dataTypes
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    array(
        'conditions' => "id = ?",
        'bind' => array($some_unsafe_id),
        'bindTypes' => array(PDO::PARAM_INT) //use only if you use $dataTypes param
    ),
    array(PDO::PARAM_STR)
);

```

Warning! If \$whereCondition is string it not escaped.

public boolean updateAsDict (unknown \$table, unknown \$data, [unknown \$whereCondition], [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Updates data on a table using custom RBDM SQL syntax Another, more convenient syntax

```

<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array(
        "name" => "New Astro Boy"
    ),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101

```

`public boolean delete (unknown $table, [unknown $whereCondition], [unknown $placeholders], [unknown $dataTypes])` inherited from Phalcon\Db\Adapter

Deletes data from a table using custom RBDM SQL syntax

```
<?php

//Deleting existing robot
$success = $connection->delete(
    "robots",
    "id = 101"
);

//Next SQL sentence is generated
DELETE FROM `robots` WHERE `id` = 101
```

`public string getColumnList (unknown $columnList)` inherited from Phalcon\Db\Adapter

Gets a list of columns

`public string limit (unknown $sqlQuery, unknown $number)` inherited from Phalcon\Db\Adapter

Appends a LIMIT clause to \$sqlQuery argument

```
<?php

echo $connection->limit ("SELECT * FROM robots", 5);
```

`public boolean tableExists (unknown $tableName, [unknown $schemaName])` inherited from Phalcon\Db\Adapter

Generates SQL checking for the existence of a schema.table

```
<?php

var_dump ($connection->tableExists ("blog", "posts"));
```

`public boolean viewExists (unknown $viewName, [unknown $schemaName])` inherited from Phalcon\Db\Adapter

Generates SQL checking for the existence of a schema.view

```
<?php

var_dump ($connection->viewExists ("active_users", "posts"));
```

`public string forUpdate (unknown $sqlQuery)` inherited from Phalcon\Db\Adapter

Returns a SQL modified with a FOR UPDATE clause

`public string sharedLock (unknown $sqlQuery)` inherited from Phalcon\Db\Adapter

Returns a SQL modified with a LOCK IN SHARE MODE clause

`public boolean createTable (unknown $tableName, unknown $schemaName, unknown $definition)` inherited from Phalcon\Db\Adapter

Creates a table

`public boolean dropTable (unknown $tableName, [unknown $schemaName], [unknown $IfExists])` inherited from Phalcon\Db\Adapter

Drops a table from a schema/database

`public boolean createView (unknown $viewName, unknown $definition, [unknown $schemaName])` inherited from Phalcon\Db\Adapter

Creates a view

`public boolean dropView (unknown $viewName, [unknown $schemaName], [unknown $IfExists])` inherited from Phalcon\Db\Adapter

Drops a view

`public boolean addColumn (unknown $tableName, unknown $schemaName, unknown $column)` inherited from Phalcon\Db\Adapter

Adds a column to a table

`public boolean modifyColumn (unknown $tableName, unknown $schemaName, unknown $column)` inherited from Phalcon\Db\Adapter

Modifies a table column based on a definition

`public boolean dropColumn (unknown $tableName, unknown $schemaName, unknown $columnName)` inherited from Phalcon\Db\Adapter

Drops a column from a table

`public boolean addIndex (unknown $tableName, unknown $schemaName, unknown $index)` inherited from Phalcon\Db\Adapter

Adds an index to a table

`public boolean dropIndex (unknown $tableName, unknown $schemaName, unknown $indexName)` inherited from Phalcon\Db\Adapter

Drop an index from a table

`public boolean addPrimaryKey (unknown $tableName, unknown $schemaName, unknown $index)` inherited from Phalcon\Db\Adapter

Adds a primary key to a table

`public boolean dropPrimaryKey (unknown $tableName, unknown $schemaName)` inherited from Phalcon\Db\Adapter

Drops a table's primary key

`public boolean true addForeignKey (unknown $tableName, unknown $schemaName, unknown $reference)` inherited from Phalcon\Db\Adapter

Adds a foreign key to a table

`public boolean true dropForeignKey (unknown $tableName, unknown $schemaName, unknown $referenceName)` inherited from Phalcon\Db\Adapter

Drops a foreign key from a table

`public string getColumnDefinition (unknown $column)` inherited from Phalcon\Db\Adapter

Returns the SQL column definition from a column

`public array listTables ([unknown $schemaName])` inherited from Phalcon\Db\Adapter

List all tables on a database

```
<?php  
    print_r($connection->listTables("blog"));
```

`public array listViews ([unknown $schemaName])` inherited from Phalcon\Db\Adapter

List all views on a database

```
<?php
print_r($connection->listViews("blog"));
```

public **Phalcon\Db\Index** [] **describeIndexes** (*unknown \$table*, [*unknown \$schema*]) inherited from Phalcon\Db\Adapter

Lists table indexes

```
<?php
print_r($connection->describeIndexes('robots_parts'));
```

public **Phalcon\Db\Reference** [] **describeReferences** (*unknown \$table*, [*unknown \$schema*]) inherited from Phalcon\Db\Adapter

Lists table references

```
<?php
print_r($connection->describeReferences('robots_parts'));
```

public *array* **tableOptions** (*unknown \$tableName*, [*unknown \$schemaName*]) inherited from Phalcon\Db\Adapter

Gets creation options from a table

```
<?php
print_r($connection->tableOptions('robots'));
```

public *boolean* **createSavepoint** (*unknown \$name*) inherited from Phalcon\Db\Adapter

Creates a new savepoint

public *boolean* **releaseSavepoint** (*unknown \$name*) inherited from Phalcon\Db\Adapter

Releases given savepoint

public *boolean* **rollbackSavepoint** (*unknown \$name*) inherited from Phalcon\Db\Adapter

Rollbacks given savepoint

public **Phalcon\Db\AdapterInterface** **setNestedTransactionsWithSavepoints** (*unknown \$nestedTransactionsWithSavepoints*) inherited from Phalcon\Db\Adapter

Set if nested transactions should use savepoints

public *boolean* **isNestedTransactionsWithSavepoints** () inherited from Phalcon\Db\Adapter

Returns if nested transactions should use savepoints

public *string* **getNestedTransactionSavepointName** () inherited from Phalcon\Db\Adapter

Returns the savepoint name to use for nested transactions

public **Phalcon\Db\RawValue** **getDefaultIdValue** () inherited from Phalcon\Db\Adapter

Returns the default identity value to be inserted in an identity column

```
<?php
//Inserting a new robot with a valid default value for the column 'id'
$success = $connection->insert(
    "robots",
    array($connection->getDefaultIdValue(), "Astro Boy", 1952),
```

```
    array("id", "name", "year")
);
```

public boolean supportSequences () inherited from Phalcon\Db\Adapter

Check whether the database system requires a sequence to produce auto-numeric values

public boolean useExplicitIdValue () inherited from Phalcon\Db\Adapter

Check whether the database system requires an explicit value for identity columns

public array getDescriptor () inherited from Phalcon\Db\Adapter

Return descriptor used to connect to the active database

public string getConnectionId () inherited from Phalcon\Db\Adapter

Gets the active connection unique identifier

public string getSQLStatement () inherited from Phalcon\Db\Adapter

Active SQL statement in the object

public string getRealSQLStatement () inherited from Phalcon\Db\Adapter

Active SQL statement in the object without replace bound parameters

public array getSQLBindTypes () inherited from Phalcon\Db\Adapter

Active SQL statement in the object

2.58.59 Class Phalcon\Db\Adapter\Pdo\Oracle

extends abstract class Phalcon\Db\Adapter\Pdo

implements Phalcon\Events\EventsAwareInterface, Phalcon\Db\AdapterInterface

Specific functions for the Oracle database system

```
<?php

$config = array(
    "dbname" => "//localhost/dbname",
    "username" => "oracle",
    "password" => "oracle"
);

$connection = new \Phalcon\Db\Adapter\Pdo\Oracle($config);
```

Methods

public boolean connect ([*unknown* \$descriptor])

This method is automatically called in Phalcon\Db\Adapter\Pdo constructor. Call it when you need to restore a database connection.

public Phalcon\Db\Column [] describeColumns (*unknown* \$table, [*unknown* \$schema])

Returns an array of Phalcon\Db\Column objects describing a table <code>print_r(\$connection->describeColumns("posts")); ?>

public int lastInsertId ([*unknown* \$sequenceName])

Returns the insert id for the auto_increment/serial column inserted in the lastest executed SQL statement

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array("Astro Boy", 1952),
    array("name", "year")
);

//Getting the generated id
$id = $connection->lastInsertId();
```

public boolean useExplicitIdValue ()

Check whether the database system requires an explicit value for identity columns

public Phalcon\Db\RawValue getDefaultIdValue ()

Return the default identity value to insert in an identity column

public boolean supportSequences ()

Check whether the database system requires a sequence to produce auto-numeric values

public __construct (unknown \$descriptor) inherited from Phalcon\Db\Adapter\Pdo

Constructor for Phalcon\Db\Adapter\Pdo

public PDOStatement prepare (unknown \$sqlStatement) inherited from Phalcon\Db\Adapter\Pdo

Returns a PDO prepared statement to be executed with ‘executePrepared’

```
<?php

$statement = $db->prepare('SELECT * FROM robots WHERE name = :name');
$result = $connection->executePrepared($statement, array('name' => 'Voltron'));
```

public PDOStatement executePrepared (unknown \$statement, unknown \$placeholders, unknown \$dataTypes) inherited from Phalcon\Db\Adapter\Pdo

Executes a prepared statement binding. This function uses integer indexes starting from zero

```
<?php

$statement = $db->prepare('SELECT * FROM robots WHERE name = :name');
$result = $connection->executePrepared($statement, array('name' => 'Voltron'));
```

public Phalcon\Db\ResultInterface|bool query (unknown \$sqlStatement, [unknown \$bindParams], [unknown \$bindTypes]) inherited from Phalcon\Db\Adapter\Pdo

Sends SQL statements to the database server returning the success state. Use this method only when the SQL statement sent to the server is returning rows

```
<?php

//Querying data
$resultset = $connection->query("SELECT * FROM robots WHERE type='mechanical'");
$resultset = $connection->query("SELECT * FROM robots WHERE type=?", array("mechanical"));
```

public boolean execute (unknown \$sqlStatement, [unknown \$bindParams], [unknown \$bindTypes]) inherited from Phalcon\Db\Adapter\Pdo

Sends SQL statements to the database server returning the success state. Use this method only when the SQL statement sent to the server doesn't return any row

```
<?php  
  
//Inserting data  
$success = $connection->execute("INSERT INTO robots VALUES (1, 'Astro Boy')");  
$success = $connection->execute("INSERT INTO robots VALUES (?, ?)", array(1, 'Astro Boy'));
```

public int affectedRows () inherited from Phalcon\Db\Adapter\Pdo

Returns the number of affected rows by the lastest INSERT/UPDATE/DELETE executed in the database system

```
<?php  
  
$connection->execute("DELETE FROM robots");  
echo $connection->affectedRows(), ' were deleted';
```

public boolean close () inherited from Phalcon\Db\Adapter\Pdo

Closes the active connection returning success. Phalcon automatically closes and destroys active connections when the request ends

public string escapeIdentifier (*unknown \$identifier*) inherited from Phalcon\Db\Adapter\Pdo

Escapes a column/table/schema name

```
<?php  
  
$escapedTable = $connection->escapeIdentifier('robots');  
$escapedTable = $connection->escapeIdentifier(array('store', 'robots'));
```

public string escapeString (*unknown \$str*) inherited from Phalcon\Db\Adapter\Pdo

Escapes a value to avoid SQL injections according to the active charset in the connection

```
<?php  
  
$escapedStr = $connection->escapeString('some dangerous value');
```

public array convertBoundParams (*string \$sql, [array \$params]*) inherited from Phalcon\Db\Adapter\Pdo

Converts bound parameters such as :name: or ?1 into PDO bind params ?

```
<?php  
  
print_r($connection->convertBoundParams('SELECT * FROM robots WHERE name = :name:', array('Bender')));
```

public boolean begin ([*unknown \$nesting*]) inherited from Phalcon\Db\Adapter\Pdo

Starts a transaction in the connection

public boolean rollback ([*unknown \$nesting*]) inherited from Phalcon\Db\Adapter\Pdo

Rollbacks the active transaction in the connection

public boolean commit ([*unknown \$nesting*]) inherited from Phalcon\Db\Adapter\Pdo

Commits the active transaction in the connection

public int getTransactionLevel () inherited from Phalcon\Db\Adapter\Pdo

Returns the current transaction nesting level

public boolean isUnderTransaction () inherited from Phalcon\Db\Adapter\Pdo

Checks whether the connection is under a transaction

```
<?php
$connection->begin();
var_dump($connection->isUnderTransaction()); //true
```

public PDO getInternalHandler () inherited from Phalcon\Db\Adapter\Pdo

Return internal PDO handler

public array getErrorInfo () inherited from Phalcon\Db\Adapter\Pdo

Return the error info, if any

public getDialectType () inherited from Phalcon\Db\Adapter

Name of the dialect used

public getType () inherited from Phalcon\Db\Adapter

Type of database system the adapter is used for

public getSqlVariables () inherited from Phalcon\Db\Adapter

Active SQL bound parameter variables

public setEventsManager (unknown \$eventsManager) inherited from Phalcon\Db\Adapter

Sets the event manager

public Phalcon\Events\ManagerInterface getEventsManager () inherited from Phalcon\Db\Adapter

Returns the internal event manager

public setDialect (unknown \$dialect) inherited from Phalcon\Db\Adapter

Sets the dialect used to produce the SQL

public Phalcon\Db\DialectInterface getDialect () inherited from Phalcon\Db\Adapter

Returns internal dialect instance

public array fetchOne (unknown \$sqlQuery, [unknown \$fetchMode], [unknown \$bindParams], [unknown \$bindTypes]) inherited from Phalcon\Db\Adapter

Returns the first row in a SQL query result

```
<?php
//Getting first robot
$robot = $connection->fetchOne("SELECT * FROM robots");
print_r($robot);

//Getting first robot with associative indexes only
$robot = $connection->fetchOne("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
print_r($robot);
```

public array fetchAll (unknown \$sqlQuery, [unknown \$fetchMode], [unknown \$bindParams], [unknown \$bindTypes]) inherited from Phalcon\Db\Adapter

Dumps the complete result of a query into an array

```
<?php
//Getting all robots with associative indexes only
```

```
$robots = $connection->fetchAll("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
foreach ($robots as $robot) {
    print_r($robot);
}

//Getting all robots that contains word "robot" withing the name
$robots = $connection->fetchAll("SELECT * FROM robots WHERE name LIKE :name",
    Phalcon\Db::FETCH_ASSOC,
    array('name' => '%robot%')
);
foreach($robots as $robot){
    print_r($robot);
}
```

public string fetchColumn (unknown \$sqlQuery, [unknown \$placeholders], [unknown \$column]) inherited from Phalcon\Db\Adapter

Returns the n'th field of first row in a SQL query result

```
<?php

//Getting count of robots
$robotsCount = $connection->fetchColumn("SELECT count(*) FROM robots");
print_r($robotsCount);

//Getting name of last edited robot
$robot = $connection->fetchColumn("SELECT id, name FROM robots ORDER BY modified DESC");
print_r($robot);
```

public boolean insert (unknown \$table, unknown \$values, [unknown \$fields], [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Inserts data into a table using custom RBDM SQL syntax

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array("Astro Boy", 1952),
    array("name", "year")
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);
```

public boolean insertAsDict (unknown \$table, unknown \$data, [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Inserts data into a table using custom RBDM SQL syntax Another, more convenient syntax

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array(
        "name" => "Astro Boy",
        "year" => 1952
    )
);
```

```
) ;

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);
```

public boolean update (unknown \$table, unknown \$fields, unknown \$values, [unknown \$whereCondition], [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Updates data on a table using custom RBDM SQL syntax

```
<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101

//Updating existing robot with array condition and $dataTypes
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    array(
        'conditions' => "id = ?",
        'bind' => array($some_unsafe_id),
        'bindTypes' => array(PDO::PARAM_INT) //use only if you use $dataTypes param
    ),
    array(PDO::PARAM_STR)
);
```

Warning! If \$whereCondition is string it not escaped.

public boolean updateAsDict (unknown \$table, unknown \$data, [unknown \$whereCondition], [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Updates data on a table using custom RBDM SQL syntax Another, more convenient syntax

```
<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array(
        "name" => "New Astro Boy"
    ),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101
```

public boolean delete (unknown \$table, [unknown \$whereCondition], [unknown \$placeholders], [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Deletes data from a table using custom RBDM SQL syntax

```
<?php

//Deleting existing robot
$success = $connection->delete(
    "robots",
    "id = 101"
);

//Next SQL sentence is generated
DELETE FROM `robots` WHERE `id` = 101
```

public *string* **getColumnName** (*unknown* \$columnName) inherited from Phalcon\Db\Adapter

Gets a list of columns

public *string* **limit** (*unknown* \$sqlQuery, *unknown* \$number) inherited from Phalcon\Db\Adapter

Appends a LIMIT clause to \$sqlQuery argument

```
<?php

echo $connection->limit("SELECT * FROM robots", 5);
```

public *boolean* **tableExists** (*unknown* \$tableName, [*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

Generates SQL checking for the existence of a schema.table

```
<?php

var_dump($connection->tableExists("blog", "posts"));
```

public *boolean* **viewExists** (*unknown* \$viewName, [*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

Generates SQL checking for the existence of a schema.view

```
<?php

var_dump($connection->viewExists("active_users", "posts"));
```

public *string* **forUpdate** (*unknown* \$sqlQuery) inherited from Phalcon\Db\Adapter

Returns a SQL modified with a FOR UPDATE clause

public *string* **sharedLock** (*unknown* \$sqlQuery) inherited from Phalcon\Db\Adapter

Returns a SQL modified with a LOCK IN SHARE MODE clause

public *boolean* **createTable** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$definition) inherited from Phalcon\Db\Adapter

Creates a table

public *boolean* **dropTable** (*unknown* \$tableName, [*unknown* \$schemaName], [*unknown* \$IfExists]) inherited from Phalcon\Db\Adapter

Drops a table from a schema/database

public *boolean* **createView** (*unknown* \$viewName, *unknown* \$definition, [*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

Creates a view

`public boolean dropView (unknown $viewName, [unknown $schemaName], [unknown $IfExists])` inherited from Phalcon\Db\Adapter

Drops a view

`public boolean addColumn (unknown $tableName, unknown $schemaName, unknown $column)` inherited from Phalcon\Db\Adapter

Adds a column to a table

`public boolean modifyColumn (unknown $tableName, unknown $schemaName, unknown $column)` inherited from Phalcon\Db\Adapter

Modifies a table column based on a definition

`public boolean dropColumn (unknown $tableName, unknown $schemaName, unknown $columnName)` inherited from Phalcon\Db\Adapter

Drops a column from a table

`public boolean addIndex (unknown $tableName, unknown $schemaName, unknown $index)` inherited from Phalcon\Db\Adapter

Adds an index to a table

`public boolean dropIndex (unknown $tableName, unknown $schemaName, unknown $indexName)` inherited from Phalcon\Db\Adapter

Drop an index from a table

`public boolean addPrimaryKey (unknown $tableName, unknown $schemaName, unknown $index)` inherited from Phalcon\Db\Adapter

Adds a primary key to a table

`public boolean dropPrimaryKey (unknown $tableName, unknown $schemaName)` inherited from Phalcon\Db\Adapter

Drops a table's primary key

`public boolean true addForeignKey (unknown $tableName, unknown $schemaName, unknown $reference)` inherited from Phalcon\Db\Adapter

Adds a foreign key to a table

`public boolean true dropForeignKey (unknown $tableName, unknown $schemaName, unknown $referenceName)` inherited from Phalcon\Db\Adapter

Drops a foreign key from a table

`public string getColumnDefinition (unknown $column)` inherited from Phalcon\Db\Adapter

Returns the SQL column definition from a column

`public array listTables ([unknown $schemaName])` inherited from Phalcon\Db\Adapter

List all tables on a database

```
<?php
print_r($connection->listTables("blog"));
```

`public array listViews ([unknown $schemaName])` inherited from Phalcon\Db\Adapter

List all views on a database

```
<?php  
print_r($connection->listViews("blog"));
```

public **Phalcon\Db\Index** [] **describeIndexes** (*unknown \$table*, [*unknown \$schema*]) inherited from Phalcon\Db\Adapter

Lists table indexes

```
<?php  
print_r($connection->describeIndexes('robots_parts'));
```

public **Phalcon\Db\Reference** [] **describeReferences** (*unknown \$table*, [*unknown \$schema*]) inherited from Phalcon\Db\Adapter

Lists table references

```
<?php  
print_r($connection->describeReferences('robots_parts'));
```

public *array* **tableOptions** (*unknown \$tableName*, [*unknown \$schemaName*]) inherited from Phalcon\Db\Adapter

Gets creation options from a table

```
<?php  
print_r($connection->tableOptions('robots'));
```

public *boolean* **createSavepoint** (*unknown \$name*) inherited from Phalcon\Db\Adapter

Creates a new savepoint

public *boolean* **releaseSavepoint** (*unknown \$name*) inherited from Phalcon\Db\Adapter

Releases given savepoint

public *boolean* **rollbackSavepoint** (*unknown \$name*) inherited from Phalcon\Db\Adapter

Rollbacks given savepoint

public **Phalcon\Db\AdapterInterface** **setNestedTransactionsWithSavepoints** (*unknown \$nestedTransactionsWithSavepoints*) inherited from Phalcon\Db\Adapter

Set if nested transactions should use savepoints

public *boolean* **isNestedTransactionsWithSavepoints** () inherited from Phalcon\Db\Adapter

Returns if nested transactions should use savepoints

public *string* **getNestedTransactionSavepointName** () inherited from Phalcon\Db\Adapter

Returns the savepoint name to use for nested transactions

public *array* **getDescriptor** () inherited from Phalcon\Db\Adapter

Return descriptor used to connect to the active database

public *string* **getConnectionId** () inherited from Phalcon\Db\Adapter

Gets the active connection unique identifier

public *string* **getSQLStatement** () inherited from Phalcon\Db\Adapter

Active SQL statement in the object

public *string* **getRealSQLStatement** () inherited from Phalcon\Db\Adapter
 Active SQL statement in the object without replace bound parameters
 public *array* **getSQLBindTypes** () inherited from Phalcon\Db\Adapter
 Active SQL statement in the object

2.58.60 Class Phalcon\Db\Adapter\Pdo\Postgresql

extends abstract class Phalcon\Db\Adapter\Pdo
implements Phalcon\Events\EventsAwareInterface, Phalcon\Db\AdapterInterface
 Specific functions for the Postgresql database system

```
<?php

$config = array(
    "host" => "192.168.0.11",
    "dbname" => "blog",
    "username" => "postgres",
    "password" => ""
);

$connection = new \Phalcon\Db\Adapter\Pdo\Postgresql($config);
```

Methods

public *boolean* **connect** ([*array* \$descriptor])

This method is automatically called in Phalcon\Db\Adapter\Pdo constructor. Call it when you need to restore a database connection.

public Phalcon\Db\Column [] **describeColumns** (*unknown* \$table, [*unknown* \$schema])

Returns an array of Phalcon\Db\Column objects describing a table

```
<?php

print_r($connection->describeColumns("posts"));
```

public *boolean* **useExplicitIdValue** ()

Check whether the database system requires an explicit value for identity columns

public Phalcon\Db\RawValue **getDefaultIdValue** ()

Returns the default identity value to be inserted in an identity column

```
<?php

//Inserting a new robot with a valid default value for the column 'id'
$success = $connection->insert(
    "robots",
    array($connection->getDefaultIdValue(), "Astro Boy", 1952),
    array("id", "name", "year")
);
```

public *boolean* supportSequences ()

Check whether the database system requires a sequence to produce auto-numeric values

public __construct (*unknown* \$descriptor) inherited from Phalcon\Db\Adapter\Pdo

Constructor for Phalcon\Db\Adapter\Pdo

public PDOStatement prepare (*unknown* \$sqlStatement) inherited from Phalcon\Db\Adapter\Pdo

Returns a PDO prepared statement to be executed with 'executePrepared'

```
<?php
```

```
$statement = $db->prepare('SELECT * FROM robots WHERE name = :name');
$result = $connection->executePrepared($statement, array('name' => 'Voltron'));
```

public PDOStatement executePrepared (*unknown* \$statement, *unknown* \$placeholders, *unknown* \$dataTypes) inherited from Phalcon\Db\Adapter\Pdo

Executes a prepared statement binding. This function uses integer indexes starting from zero

```
<?php
```

```
$statement = $db->prepare('SELECT * FROM robots WHERE name = :name');
$result = $connection->executePrepared($statement, array('name' => 'Voltron'));
```

public Phalcon\Db\ResultInterface |bool query (*unknown* \$sqlStatement, [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter\Pdo

Sends SQL statements to the database server returning the success state. Use this method only when the SQL statement sent to the server is returning rows

```
<?php
```

```
//Querying data
$resultset = $connection->query("SELECT * FROM robots WHERE type='mechanical'");
$resultset = $connection->query("SELECT * FROM robots WHERE type=?", array("mechanical"));
```

public *boolean* execute (*unknown* \$sqlStatement, [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter\Pdo

Sends SQL statements to the database server returning the success state. Use this method only when the SQL statement sent to the server doesn't return any row

```
<?php
```

```
//Inserting data
$success = $connection->execute("INSERT INTO robots VALUES (1, 'Astro Boy')");
$success = $connection->execute("INSERT INTO robots VALUES (?, ?)", array(1, 'Astro Boy'));
```

public *int* affectedRows () inherited from Phalcon\Db\Adapter\Pdo

Returns the number of affected rows by the lastest INSERT/UPDATE/DELETE executed in the database system

```
<?php
```

```
$connection->execute("DELETE FROM robots");
echo $connection->affectedRows(), ' were deleted';
```

public *boolean* close () inherited from Phalcon\Db\Adapter\Pdo

Closes the active connection returning success. Phalcon automatically closes and destroys active connections when the request ends

public string escapeIdentifier (*unknown \$identifier*) inherited from Phalcon\Db\Adapter\Pdo

Escapes a column/table/schema name

```
<?php

$escapedTable = $connection->escapeIdentifier('robots');
$escapedTable = $connection->escapeIdentifier(array('store', 'robots'));
```

public string escapeString (*unknown \$str*) inherited from Phalcon\Db\Adapter\Pdo

Escapes a value to avoid SQL injections according to the active charset in the connection

```
<?php

$escapedStr = $connection->escapeString('some dangerous value');
```

public array convertBoundParams (*string \$sql, [array \$params]*) inherited from Phalcon\Db\Adapter\Pdo

Converts bound parameters such as :name: or ?1 into PDO bind params ?

```
<?php

print_r($connection->convertBoundParams('SELECT * FROM robots WHERE name = :name:', array('Bender')));
```

public int|boolean lastInsertId ([*unknown \$sequenceName*]) inherited from Phalcon\Db\Adapter\Pdo

Returns the insert id for the auto_increment/serial column inserted in the lastest executed SQL statement

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array("Astro Boy", 1952),
    array("name", "year")
);

//Getting the generated id
$id = $connection->lastInsertId();
```

public boolean begin ([*unknown \$nesting*]) inherited from Phalcon\Db\Adapter\Pdo

Starts a transaction in the connection

public boolean rollback ([*unknown \$nesting*]) inherited from Phalcon\Db\Adapter\Pdo

Rollbacks the active transaction in the connection

public boolean commit ([*unknown \$nesting*]) inherited from Phalcon\Db\Adapter\Pdo

Commits the active transaction in the connection

public int getTransactionLevel () inherited from Phalcon\Db\Adapter\Pdo

Returns the current transaction nesting level

public boolean isUnderTransaction () inherited from Phalcon\Db\Adapter\Pdo

Checks whether the connection is under a transaction

```
<?php

$connection->begin();
var_dump($connection->isUnderTransaction()); //true
```

public **PDO** **getInternalHandler** () inherited from Phalcon\Db\Adapter\Pdo

Return internal PDO handler

public **array** **getInfo** () inherited from Phalcon\Db\Adapter\Pdo

Return the error info, if any

public **getDialectType** () inherited from Phalcon\Db\Adapter

Name of the dialect used

public **getType** () inherited from Phalcon\Db\Adapter

Type of database system the adapter is used for

public **getSqlVariables** () inherited from Phalcon\Db\Adapter

Active SQL bound parameter variables

public **setEventsManager** (*unknown* \$eventsManager) inherited from Phalcon\Db\Adapter

Sets the event manager

public **Phalcon\Events\ManagerInterface** **getEventsManager** () inherited from Phalcon\Db\Adapter

Returns the internal event manager

public **setDialect** (*unknown* \$dialect) inherited from Phalcon\Db\Adapter

Sets the dialect used to produce the SQL

public **Phalcon\Db\DialectInterface** **getDialect** () inherited from Phalcon\Db\Adapter

Returns internal dialect instance

public **array** **fetchOne** (*unknown* \$sqlQuery, [*unknown* \$fetchMode], [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter

Returns the first row in a SQL query result

```
<?php

//Getting first robot
$robot = $connection->fetchOne("SELECT * FROM robots");
print_r($robot);

//Getting first robot with associative indexes only
$robot = $connection->fetchOne("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
print_r($robot);
```

public **array** **fetchAll** (*unknown* \$sqlQuery, [*unknown* \$fetchMode], [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter

Dumps the complete result of a query into an array

```
<?php

//Getting all robots with associative indexes only
$robots = $connection->fetchAll("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
foreach ($robots as $robot) {
    print_r($robot);
}

//Getting all robots that contains word "robot" withing the name
$robots = $connection->fetchAll("SELECT * FROM robots WHERE name LIKE :name",
```

```

Phalcon\Db::FETCH_ASSOC,
array('name' => '%robot%')
);
foreach($robots as $robot) {
    print_r($robot);
}

```

`public string|fetchColumn (unknown $sqlQuery, [unknown $placeholders], [unknown $column])` inherited from Phalcon\Db\Adapter

Returns the n'th field of first row in a SQL query result

```

<?php

//Getting count of robots
$robotsCount = $connection->fetchColumn("SELECT count(*) FROM robots");
print_r($robotsCount);

//Getting name of last edited robot
$robot = $connection->fetchColumn("SELECT id, name FROM robots ORDER BY modified DESC");
print_r($robot);

```

`public boolean insert (unknown $table, unknown $values, [unknown $fields], [unknown $dataTypes])` inherited from Phalcon\Db\Adapter

Inserts data into a table using custom RBDM SQL syntax

```

<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array("Astro Boy", 1952),
    array("name", "year")
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);

```

`public boolean insertAsDict (unknown $table, unknown $data, [unknown $dataTypes])` inherited from Phalcon\Db\Adapter

Inserts data into a table using custom RBDM SQL syntax Another, more convenient syntax

```

<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array(
        "name" => "Astro Boy",
        "year" => 1952
    )
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);

```

`public boolean update (unknown $table, unknown $fields, unknown $values, [unknown $whereCondition], [unknown $dataTypes])` inherited from Phalcon\Db\Adapter

Updates data on a table using custom RBDM SQL syntax

```
<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101

//Updating existing robot with array condition and $dataTypes
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    array(
        'conditions' => "id = ?",
        'bind' => array($some_unsafe_id),
        'bindTypes' => array(PDO::PARAM_INT) //use only if you use $dataTypes param
    ),
    array(PDO::PARAM_STR)
);
```

Warning! If \$whereCondition is string it not escaped.

`public boolean updateAsDict (unknown $table, unknown $data, [unknown $whereCondition], [unknown $dataTypes])`
inherited from Phalcon\Db\Adapter

Updates data on a table using custom RBDM SQL syntax Another, more convenient syntax

```
<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array(
        "name" => "New Astro Boy"
    ),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101
```

`public boolean delete (unknown $table, [unknown $whereCondition], [unknown $placeholders], [unknown $dataTypes])`
inherited from Phalcon\Db\Adapter

Deletes data from a table using custom RBDM SQL syntax

```
<?php

//Deleting existing robot
$success = $connection->delete(
    "robots",
    "id = 101"
```

```
) ;

//Next SQL sentence is generated
DELETE FROM `robots` WHERE `id` = 101
```

public string getColumnList (unknown \$columnList) inherited from Phalcon\Db\Adapter

Gets a list of columns

public string limit (unknown \$sqlQuery, unknown \$number) inherited from Phalcon\Db\Adapter

Appends a LIMIT clause to \$sqlQuery argument

```
<?php

echo $connection->limit ("SELECT * FROM robots", 5);
```

public boolean tableExists (unknown \$tableName, [unknown \$schemaName]) inherited from Phalcon\Db\Adapter

Generates SQL checking for the existence of a schema.table

```
<?php

var_dump ($connection->tableExists ("blog", "posts"));
```

public boolean viewExists (unknown \$viewName, [unknown \$schemaName]) inherited from Phalcon\Db\Adapter

Generates SQL checking for the existence of a schema.view

```
<?php

var_dump ($connection->viewExists ("active_users", "posts"));
```

public string forUpdate (unknown \$sqlQuery) inherited from Phalcon\Db\Adapter

Returns a SQL modified with a FOR UPDATE clause

public string sharedLock (unknown \$sqlQuery) inherited from Phalcon\Db\Adapter

Returns a SQL modified with a LOCK IN SHARE MODE clause

public boolean createTable (unknown \$tableName, unknown \$schemaName, unknown \$definition) inherited from Phalcon\Db\Adapter

Creates a table

public boolean dropTable (unknown \$tableName, [unknown \$schemaName], [unknown \$IfExists]) inherited from Phalcon\Db\Adapter

Drops a table from a schema/database

public boolean createView (unknown \$viewName, unknown \$definition, [unknown \$schemaName]) inherited from Phalcon\Db\Adapter

Creates a view

public boolean dropView (unknown \$viewName, [unknown \$schemaName], [unknown \$IfExists]) inherited from Phalcon\Db\Adapter

Drops a view

public boolean addColumn (unknown \$tableName, unknown \$schemaName, unknown \$column) inherited from Phalcon\Db\Adapter

Adds a column to a table

public *boolean* **modifyColumn** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$column) inherited from Phalcon\Db\Adapter

Modifies a table column based on a definition

public *boolean* **dropColumn** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$columnName) inherited from Phalcon\Db\Adapter

Drops a column from a table

public *boolean* **addIndex** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$index) inherited from Phalcon\Db\Adapter

Adds an index to a table

public *boolean* **dropIndex** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$indexName) inherited from Phalcon\Db\Adapter

Drop an index from a table

public *boolean* **addPrimaryKey** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$index) inherited from Phalcon\Db\Adapter

Adds a primary key to a table

public *boolean* **dropPrimaryKey** (*unknown* \$tableName, *unknown* \$schemaName) inherited from Phalcon\Db\Adapter

Drops a table's primary key

public *boolean* **true addForeignKey** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$reference) inherited from Phalcon\Db\Adapter

Adds a foreign key to a table

public *boolean* **true dropForeignKey** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$referenceName) inherited from Phalcon\Db\Adapter

Drops a foreign key from a table

public *string* **getColumnDefinition** (*unknown* \$column) inherited from Phalcon\Db\Adapter

Returns the SQL column definition from a column

public *array* **listTables** ([*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

List all tables on a database

```
<?php  
print_r($connection->listTables("blog"));
```

public *array* **listViews** ([*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

List all views on a database

```
<?php  
print_r($connection->listViews("blog"));
```

public *Phalcon\Db\Index* [] **describeIndexes** (*unknown* \$table, [*unknown* \$schema]) inherited from Phalcon\Db\Adapter

Lists table indexes

```
<?php
print_r($connection->describeIndexes('robots_parts'));
```

public Phalcon\Db\Reference [] describeReferences (*unknown \$table*, [*unknown \$schema*]) inherited from Phalcon\Db\Adapter

Lists table references

```
<?php
print_r($connection->describeReferences('robots_parts'));
```

public array tableOptions (*unknown \$tableName*, [*unknown \$schemaName*]) inherited from Phalcon\Db\Adapter

Gets creation options from a table

```
<?php
print_r($connection->tableOptions('robots'));
```

public boolean createSavepoint (*unknown \$name*) inherited from Phalcon\Db\Adapter

Creates a new savepoint

public boolean releaseSavepoint (*unknown \$name*) inherited from Phalcon\Db\Adapter

Releases given savepoint

public boolean rollbackSavepoint (*unknown \$name*) inherited from Phalcon\Db\Adapter

Rollbacks given savepoint

public Phalcon\Db\AdapterInterface setNestedTransactionsWithSavepoints (*unknown \$nestedTransactionsWithSavepoints*) inherited from Phalcon\Db\Adapter

Set if nested transactions should use savepoints

public boolean isNestedTransactionsWithSavepoints () inherited from Phalcon\Db\Adapter

Returns if nested transactions should use savepoints

public string getNestedTransactionSavepointName () inherited from Phalcon\Db\Adapter

Returns the savepoint name to use for nested transactions

public array getDescriptor () inherited from Phalcon\Db\Adapter

Return descriptor used to connect to the active database

public string getConnectionId () inherited from Phalcon\Db\Adapter

Gets the active connection unique identifier

public string getSQLStatement () inherited from Phalcon\Db\Adapter

Active SQL statement in the object

public string getRealSQLStatement () inherited from Phalcon\Db\Adapter

Active SQL statement in the object without replace bound parameters

public array getSQLBindTypes () inherited from Phalcon\Db\Adapter

Active SQL statement in the object

2.58.61 Class Phalcon\Db\Adapter\Pdo\Sqlite

extends abstract class `Phalcon\Db\Adapter\Pdo`

implements `Phalcon\Events\EventsAwareInterface`, `Phalcon\Db\AdapterInterface`

Specific functions for the Sqlite database system

```
<?php

$config = array(
    "dbname" => "/tmp/test.sqlite"
);

$connection = new \Phalcon\Db\Adapter\Pdo\Sqlite($config);
```

Methods

`public boolean connect ([array $descriptor])`

This method is automatically called in `Phalcon\Db\Adapter\Pdo` constructor. Call it when you need to restore a database connection.

`public Phalcon\Db\Column [] describeColumns (unknown $table, [unknown $schema])`

Returns an array of `Phalcon\Db\Column` objects describing a table

```
<?php

print_r($connection->describeColumns ("posts"));
```

`public Phalcon\Db\IndexInterface [] describeIndexes (unknown $table, [unknown $schema])`

Lists table indexes

`public Phalcon\Db\ReferenceInterface [] describeReferences (unknown $table, [unknown $schema])`

Lists table references

`public boolean useExplicitIdValue ()`

Check whether the database system requires an explicit value for identity columns

`public __construct (unknown $descriptor)` inherited from `Phalcon\Db\Adapter\Pdo`

Constructor for `Phalcon\Db\Adapter\Pdo`

`public PDOStatement prepare (unknown $sqlStatement)` inherited from `Phalcon\Db\Adapter\Pdo`

Returns a PDO prepared statement to be executed with ‘executePrepared’

```
<?php

$statement = $db->prepare ('SELECT * FROM robots WHERE name = :name');
$result = $connection->executePrepared($statement, array('name' => 'Voltron'));
```

`public PDOStatement executePrepared (unknown $statement, unknown $placeholders, unknown $dataTypes)` inherited from `Phalcon\Db\Adapter\Pdo`

Executes a prepared statement binding. This function uses integer indexes starting from zero

```
<?php

$statement = $db->prepare('SELECT * FROM robots WHERE name = :name');
$result = $connection->executePrepared($statement, array('name' => 'Voltron'));
```

public Phalcon\Db\ResultInterface |bool query (*unknown* \$sqlStatement, [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter\Pdo

Sends SQL statements to the database server returning the success state. Use this method only when the SQL statement sent to the server is returning rows

```
<?php

//Querying data
$resultset = $connection->query("SELECT * FROM robots WHERE type='mechanical'");
$resultset = $connection->query("SELECT * FROM robots WHERE type=?", array("mechanical"));
```

public boolean execute (*unknown* \$sqlStatement, [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter\Pdo

Sends SQL statements to the database server returning the success state. Use this method only when the SQL statement sent to the server doesn't return any row

```
<?php

//Inserting data
$success = $connection->execute("INSERT INTO robots VALUES (1, 'Astro Boy')");
$success = $connection->execute("INSERT INTO robots VALUES (?, ?)", array(1, 'Astro Boy'));
```

public int affectedRows () inherited from Phalcon\Db\Adapter\Pdo

Returns the number of affected rows by the lastest INSERT/UPDATE/DELETE executed in the database system

```
<?php

$connection->execute("DELETE FROM robots");
echo $connection->affectedRows(), ' were deleted';
```

public boolean close () inherited from Phalcon\Db\Adapter\Pdo

Closes the active connection returning success. Phalcon automatically closes and destroys active connections when the request ends

public string escapeIdentifier (*unknown* \$identifier) inherited from Phalcon\Db\Adapter\Pdo

Escapes a column/table/schema name

```
<?php

$escapedTable = $connection->escapeIdentifier('robots');
$escapedTable = $connection->escapeIdentifier(array('store', 'robots'));
```

public string escapeString (*unknown* \$str) inherited from Phalcon\Db\Adapter\Pdo

Escapes a value to avoid SQL injections according to the active charset in the connection

```
<?php

$escapedStr = $connection->escapeString('some dangerous value');
```

public array convertBoundParams (*string* \$sql, [*array* \$params]) inherited from Phalcon\Db\Adapter\Pdo

Converts bound parameters such as :name: or ?1 into PDO bind params ?

```
<?php  
  
print_r($connection->convertBoundParams('SELECT * FROM robots WHERE name = :name:', array('Bender')));
```

public *int|boolean* **lastInsertId** ([*unknown* \$sequenceName]) inherited from Phalcon\Db\Adapter\Pdo

Returns the insert id for the auto_increment/serial column inserted in the lastest executed SQL statement

```
<?php  
  
//Inserting a new robot  
$success = $connection->insert(  
    "robots",  
    array("Astro Boy", 1952),  
    array("name", "year")  
);  
  
//Getting the generated id  
$id = $connection->lastInsertId();
```

public *boolean* **begin** ([*unknown* \$nesting]) inherited from Phalcon\Db\Adapter\Pdo

Starts a transaction in the connection

public *boolean* **rollback** ([*unknown* \$nesting]) inherited from Phalcon\Db\Adapter\Pdo

Rollbacks the active transaction in the connection

public *boolean* **commit** ([*unknown* \$nesting]) inherited from Phalcon\Db\Adapter\Pdo

Commits the active transaction in the connection

public *int* **getTransactionLevel** () inherited from Phalcon\Db\Adapter\Pdo

Returns the current transaction nesting level

public *boolean* **isUnderTransaction** () inherited from Phalcon\Db\Adapter\Pdo

Checks whether the connection is under a transaction

```
<?php  
  
$connection->begin();  
var_dump($connection->isUnderTransaction()); //true
```

public *PDO* **getInternalHandler** () inherited from Phalcon\Db\Adapter\Pdo

Return internal PDO handler

public *array* **getErrorHandler** () inherited from Phalcon\Db\Adapter\Pdo

Return the error info, if any

public **getDialectType** () inherited from Phalcon\Db\Adapter

Name of the dialect used

public **getType** () inherited from Phalcon\Db\Adapter

Type of database system the adapter is used for

public **getSqlVariables** () inherited from Phalcon\Db\Adapter

Active SQL bound parameter variables

public **setEventsManager** (*unknown* \$eventsManager) inherited from Phalcon\Db\Adapter

Sets the event manager

public Phalcon\Events\ManagerInterface **getEventsManager** () inherited from Phalcon\Db\Adapter

Returns the internal event manager

public **setDialect** (*unknown* \$dialect) inherited from Phalcon\Db\Adapter

Sets the dialect used to produce the SQL

public Phalcon\Db\ManagerInterface **getDialect** () inherited from Phalcon\Db\Adapter

Returns internal dialect instance

public array **fetchOne** (*unknown* \$sqlQuery, [*unknown* \$fetchMode], [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter

Returns the first row in a SQL query result

```
<?php

//Getting first robot
$robot = $connection->fetchOne("SELECT * FROM robots");
print_r($robot);

//Getting first robot with associative indexes only
$robot = $connection->fetchOne("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
print_r($robot);
```

public array **fetchAll** (*unknown* \$sqlQuery, [*unknown* \$fetchMode], [*unknown* \$bindParams], [*unknown* \$bindTypes]) inherited from Phalcon\Db\Adapter

Dumps the complete result of a query into an array

```
<?php

//Getting all robots with associative indexes only
$robots = $connection->fetchAll("SELECT * FROM robots", Phalcon\Db::FETCH_ASSOC);
foreach ($robots as $robot) {
    print_r($robot);
}

//Getting all robots that contains word "robot" withing the name
$robots = $connection->fetchAll("SELECT * FROM robots WHERE name LIKE :name",
    Phalcon\Db::FETCH_ASSOC,
    array('name' => '%robot%')
);
foreach ($robots as $robot) {
    print_r($robot);
}
```

public string|**fetchColumn** (*unknown* \$sqlQuery, [*unknown* \$placeholders], [*unknown* \$column]) inherited from Phalcon\Db\Adapter

Returns the n'th field of first row in a SQL query result

```
<?php

//Getting count of robots
$robotsCount = $connection->fetchColumn("SELECT count(*) FROM robots");
print_r($robotsCount);
```

```
//Getting name of last edited robot
$robot = $connection->fetchColumn("SELECT id, name FROM robots ORDER BY modified DESC");
print_r($robot);
```

`public boolean insert (unknown $table, unknown $values, [unknown $fields], [unknown $dataTypes])` inherited from Phalcon\Db\Adapter

Inserts data into a table using custom RBDM SQL syntax

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array("Astro Boy", 1952),
    array("name", "year")
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);
```

`public boolean insertAsDict (unknown $table, unknown $data, [unknown $dataTypes])` inherited from Phalcon\Db\Adapter

Inserts data into a table using custom RBDM SQL syntax Another, more convenient syntax

```
<?php

//Inserting a new robot
$success = $connection->insert(
    "robots",
    array(
        "name" => "Astro Boy",
        "year" => 1952
    )
);

//Next SQL sentence is sent to the database system
INSERT INTO `robots` (`name`, `year`) VALUES ("Astro boy", 1952);
```

`public boolean update (unknown $table, unknown $fields, unknown $values, [unknown $whereCondition], [unknown $dataTypes])` inherited from Phalcon\Db\Adapter

Updates data on a table using custom RBDM SQL syntax

```
<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101

//Updating existing robot with array condition and $dataTypes
```

```
$success = $connection->update(
    "robots",
    array("name"),
    array("New Astro Boy"),
    array(
        'conditions' => "id = ?",
        'bind' => array($some_unsafe_id),
        'bindTypes' => array(PDO::PARAM_INT) //use only if you use $dataTypes param
    ),
    array(PDO::PARAM_STR)
);
```

Warning! If \$whereCondition is string it not escaped.

public boolean updateAsDict (unknown \$table, unknown \$data, [unknown \$whereCondition], [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Updates data on a table using custom RBDM SQL syntax Another, more convenient syntax

```
<?php

//Updating existing robot
$success = $connection->update(
    "robots",
    array(
        "name" => "New Astro Boy"
    ),
    "id = 101"
);

//Next SQL sentence is sent to the database system
UPDATE `robots` SET `name` = "Astro boy" WHERE id = 101
```

public boolean delete (unknown \$table, [unknown \$whereCondition], [unknown \$placeholders], [unknown \$dataTypes]) inherited from Phalcon\Db\Adapter

Deletes data from a table using custom RBDM SQL syntax

```
<?php

//Deleting existing robot
$success = $connection->delete(
    "robots",
    "id = 101"
);

//Next SQL sentence is generated
DELETE FROM `robots` WHERE `id` = 101
```

public string getColumnList (unknown \$columnList) inherited from Phalcon\Db\Adapter

Gets a list of columns

public string limit (unknown \$sqlQuery, unknown \$number) inherited from Phalcon\Db\Adapter

Appends a LIMIT clause to \$sqlQuery argument

```
<?php

echo $connection->limit ("SELECT * FROM robots", 5);
```

public *boolean* **tableExists** (*unknown* \$tableName, [*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

Generates SQL checking for the existence of a schema.table

```
<?php
```

```
var_dump($connection->tableExists("blog", "posts"));
```

public *boolean* **viewExists** (*unknown* \$viewName, [*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

Generates SQL checking for the existence of a schema.view

```
<?php
```

```
var_dump($connection->viewExists("active_users", "posts"));
```

public *string* **forUpdate** (*unknown* \$sqlQuery) inherited from Phalcon\Db\Adapter

Returns a SQL modified with a FOR UPDATE clause

public *string* **sharedLock** (*unknown* \$sqlQuery) inherited from Phalcon\Db\Adapter

Returns a SQL modified with a LOCK IN SHARE MODE clause

public *boolean* **createTable** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$definition) inherited from Phalcon\Db\Adapter

Creates a table

public *boolean* **dropTable** (*unknown* \$tableName, [*unknown* \$schemaName], [*unknown* \$IfExists]) inherited from Phalcon\Db\Adapter

Drops a table from a schema/database

public *boolean* **createView** (*unknown* \$viewName, *unknown* \$definition, [*unknown* \$schemaName]) inherited from Phalcon\Db\Adapter

Creates a view

public *boolean* **dropView** (*unknown* \$viewName, [*unknown* \$schemaName], [*unknown* \$IfExists]) inherited from Phalcon\Db\Adapter

Drops a view

public *boolean* **addColumn** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$column) inherited from Phalcon\Db\Adapter

Adds a column to a table

public *boolean* **modifyColumn** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$column) inherited from Phalcon\Db\Adapter

Modifies a table column based on a definition

public *boolean* **dropColumn** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$columnName) inherited from Phalcon\Db\Adapter

Drops a column from a table

public *boolean* **addIndex** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$index) inherited from Phalcon\Db\Adapter

Adds an index to a table

public *boolean* **dropIndex** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$indexName) inherited from Phalcon\Db\Adapter

Drop an index from a table

`public boolean addPrimaryKey (unknown $tableName, unknown $schemaName, unknown $index)` inherited from Phalcon\Db\Adapter

Adds a primary key to a table

`public boolean dropPrimaryKey (unknown $tableName, unknown $schemaName)` inherited from Phalcon\Db\Adapter

Drops a table's primary key

`public boolean true addForeignKey (unknown $tableName, unknown $schemaName, unknown $reference)` inherited from Phalcon\Db\Adapter

Adds a foreign key to a table

`public boolean true dropForeignKey (unknown $tableName, unknown $schemaName, unknown $referenceName)` inherited from Phalcon\Db\Adapter

Drops a foreign key from a table

`public string getColumnDefinition (unknown $column)` inherited from Phalcon\Db\Adapter

Returns the SQL column definition from a column

`public array listTables ([unknown $schemaName])` inherited from Phalcon\Db\Adapter

List all tables on a database

```
<?php
print_r($connection->listTables("blog"));
```

`public array listViews ([unknown $schemaName])` inherited from Phalcon\Db\Adapter

List all views on a database

```
<?php
print_r($connection->listViews("blog"));
```

`public array tableOptions (unknown $tableName, [unknown $schemaName])` inherited from Phalcon\Db\Adapter

Gets creation options from a table

```
<?php
print_r($connection->tableOptions('robots'));
```

`public boolean createSavepoint (unknown $name)` inherited from Phalcon\Db\Adapter

Creates a new savepoint

`public boolean releaseSavepoint (unknown $name)` inherited from Phalcon\Db\Adapter

Releases given savepoint

`public boolean rollbackSavepoint (unknown $name)` inherited from Phalcon\Db\Adapter

Rollbacks given savepoint

`public Phalcon\Db\AdapterInterface setNestedTransactionsWithSavepoints (unknown $nestedTransactionsWithSavepoints)` inherited from Phalcon\Db\Adapter

Set if nested transactions should use savepoints

public *boolean* **isNestedTransactionsWithSavepoints** () inherited from Phalcon\Db\Adapter

Returns if nested transactions should use savepoints

public *string* **getNestedTransactionSavepointName** () inherited from Phalcon\Db\Adapter

Returns the savepoint name to use for nested transactions

public *Phalcon\Db\RawValue* **getDefaultIdValue** () inherited from Phalcon\Db\Adapter

Returns the default identity value to be inserted in an identity column

```
<?php

//Inserting a new robot with a valid default value for the column 'id'
$success = $connection->insert(
    "robots",
    array($connection->getDefaultIdValue(), "Astro Boy", 1952),
    array("id", "name", "year")
);
```

public *boolean* **supportSequences** () inherited from Phalcon\Db\Adapter

Check whether the database system requires a sequence to produce auto-numeric values

public *array* **getDescriptor** () inherited from Phalcon\Db\Adapter

Return descriptor used to connect to the active database

public *string* **getConnectionId** () inherited from Phalcon\Db\Adapter

Gets the active connection unique identifier

public *string* **getSQLStatement** () inherited from Phalcon\Db\Adapter

Active SQL statement in the object

public *string* **getRealSQLStatement** () inherited from Phalcon\Db\Adapter

Active SQL statement in the object without replace bound parameters

public *array* **getSQLBindTypes** () inherited from Phalcon\Db\Adapter

Active SQL statement in the object

2.58.62 Class Phalcon\Db\Column

implements Phalcon\Db\ColumnInterface

Allows to define columns to be used on create or alter table operations

```
<?php

use Phalcon\Db\Column as Column;

//column definition
$column = new Column("id", array(
    "type" => Column::TYPE_INTEGER,
    "size" => 10,
    "unsigned" => true,
    "notNull" => true,
    "autoIncrement" => true,
    "first" => true
));
```

```
//add column to existing table
$connection->addColumn("robots", null, $column);
```

Constants

integer **TYPE_INTEGER**
integer **TYPE_DATE**
integer **TYPE_VARCHAR**
integer **TYPE_DECIMAL**
integer **TYPE_DATETIME**
integer **TYPE_CHAR**
integer **TYPE_TEXT**
integer **TYPE_FLOAT**
integer **TYPE_BOOLEAN**
integer **BIND_PARAM_NULL**
integer **BIND_PARAM_INT**
integer **BIND_PARAM_STR**
integer **BIND_PARAM_BOOL**
integer **BIND_PARAM_DECIMAL**
integer **BIND_SKIP**

Methods

public getName ()
Column's name
public getSchemaName ()
Schema which table related is
public getType ()
Column data type
public getTypeReference ()
Column data type reference
public getTypeValues ()
Column data type values
public getSize ()
Integer column size
public getScale ()
Integer column number scale

public **getDefault** ()
Default column value

public __construct (*unknown* \$name, *unknown* \$definition)
Phalcon\Db\Column constructor

public *boolean* **isUnsigned** ()
Returns true if number column is unsigned

public *boolean* **isNotNull** ()
Not null

public *boolean* **isPrimary** ()
Column is part of the primary key?

public *boolean* **isAutoIncrement** ()
Auto-Increment

public *boolean* **isNumeric** ()
Check whether column have an numeric type

public *boolean* **isFirst** ()
Check whether column have first position in table

public *string* **getAfterPosition** ()
Check whether field absolute to position in table

public *int* **getBindType** ()
Returns the type of bind handling

public static *PhalconDbColumn* **__set_state** (*unknown* \$data)
Restores the internal state of a Phalcon\Db\Column object

2.58.63 Abstract class Phalcon\Db\Dialect

This is the base class to each database dialect. This implements common methods to transform intermediate code into its RDBM related syntax

Methods

public *string* **limit** (*unknown* \$sqlQuery, *unknown* \$number)

Generates the SQL for LIMIT clause

```
<?php  
  
$sql = $dialect->limit('SELECT * FROM robots', 10);  
echo $sql; // SELECT * FROM robots LIMIT 10
```

public *string* **forUpdate** (*unknown* \$sqlQuery)

Returns a SQL modified with a FOR UPDATE clause

```
<?php
$sql = $dialect->forUpdate('SELECT * FROM robots');
echo $sql; // SELECT * FROM robots FOR UPDATE
```

public string sharedLock (unknown \$sqlQuery)

Returns a SQL modified with a LOCK IN SHARE MODE clause

```
<?php
$sql = $dialect->sharedLock('SELECT * FROM robots');
echo $sql; // SELECT * FROM robots LOCK IN SHARE MODE
```

final public string getColumnList (unknown \$columnList)

Gets a list of columns with escaped identifiers

```
<?php
echo $dialect->getColumnList(array('column1', 'column'));
```

public string getSqlExpression (unknown \$expression, [unknown \$escapeChar])

Transforms an intermediate representation for a expression into a database system valid expression

final public string getSqlTable (unknown \$table, [unknown \$escapeChar])

Transform an intermediate representation of a schema/table into a database system valid expression

public string select (unknown \$definition)

Builds a SELECT statement

public boolean supportsSavepoints ()

Checks whether the platform supports savepoints

public boolean supportsReleaseSavepoints ()

Checks whether the platform supports releasing savepoints.

public string createSavepoint (unknown \$name)

Generate SQL to create a new savepoint

public string releaseSavepoint (unknown \$name)

Generate SQL to release a savepoint

public string rollbackSavepoint (unknown \$name)

Generate SQL to rollback a savepoint

2.58.64 Class Phalcon\Db\Dialect\Oracle

extends abstract class [Phalcon\Db\Dialect](#)

Methods

public string limit (unknown \$sqlQuery, unknown \$number) inherited from [Phalcon\Db\Dialect](#)

Generates the SQL for LIMIT clause

```
<?php  
  
$sql = $dialect->limit('SELECT * FROM robots', 10);  
echo $sql; // SELECT * FROM robots LIMIT 10
```

public *string* **forUpdate** (*unknown* \$sqlQuery) inherited from Phalcon\Db\Dialet

Returns a SQL modified with a FOR UPDATE clause

```
<?php  
  
$sql = $dialect->forUpdate('SELECT * FROM robots');  
echo $sql; // SELECT * FROM robots FOR UPDATE
```

public *string* **sharedLock** (*unknown* \$sqlQuery) inherited from Phalcon\Db\Dialet

Returns a SQL modified with a LOCK IN SHARE MODE clause

```
<?php  
  
$sql = $dialect->sharedLock('SELECT * FROM robots');  
echo $sql; // SELECT * FROM robots LOCK IN SHARE MODE
```

final public *string* **getColumnList** (*unknown* \$columnList) inherited from Phalcon\Db\Dialet

Gets a list of columns with escaped identifiers

```
<?php  
  
echo $dialect->getColumnList(array('column1', 'column'));
```

public *string* **getSqlExpression** (*unknown* \$expression, [*unknown* \$escapeChar]) inherited from Phalcon\Db\Dialet

Transforms an intermediate representation for a expression into a database system valid expression

final public *string* **getSqlTable** (*unknown* \$table, [*unknown* \$escapeChar]) inherited from Phalcon\Db\Dialet

Transform an intermediate representation of a schema/table into a database system valid expression

public *string* **select** (*unknown* \$definition) inherited from Phalcon\Db\Dialet

Builds a SELECT statement

public *boolean* **supportsSavepoints** () inherited from Phalcon\Db\Dialet

Checks whether the platform supports savepoints

public *boolean* **supportsReleaseSavepoints** () inherited from Phalcon\Db\Dialet

Checks whether the platform supports releasing savepoints.

public *string* **createSavepoint** (*unknown* \$name) inherited from Phalcon\Db\Dialet

Generate SQL to create a new savepoint

public *string* **releaseSavepoint** (*unknown* \$name) inherited from Phalcon\Db\Dialet

Generate SQL to release a savepoint

public *string* **rollbackSavepoint** (*unknown* \$name) inherited from Phalcon\Db\Dialet

Generate SQL to rollback a savepoint

2.58.65 Class Phalcon\Db\Dialect\Postgresql

extends abstract class [Phalcon\Db\Dialect](#)

implements [Phalcon\Db\DialectInterface](#)

Generates database specific SQL for the PostgreSQL RBDM

Methods

public string getColumnDefinition (unknown \$column)

Gets the column name in PostgreSQL

public string addColumn (unknown \$tableName, unknown \$schemaName, unknown \$column)

Generates SQL to add a column to a table

public string modifyColumn (unknown \$tableName, unknown \$schemaName, unknown \$column)

Generates SQL to modify a column in a table

public string dropColumn (unknown \$tableName, unknown \$schemaName, unknown \$columnName)

Generates SQL to delete a column from a table

public string addIndex (unknown \$tableName, unknown \$schemaName, unknown \$index)

Generates SQL to add an index to a table

public string dropIndex (unknown \$tableName, unknown \$schemaName, unknown \$indexName)

Generates SQL to delete an index from a table

public string addPrimaryKey (unknown \$tableName, unknown \$schemaName, unknown \$index)

Generates SQL to add the primary key to a table

public string dropPrimaryKey (unknown \$tableName, unknown \$schemaName)

Generates SQL to delete primary key from a table

public string addForeignKey (unknown \$tableName, unknown \$schemaName, unknown \$reference)

Generates SQL to add an index to a table

public string dropForeignKey (unknown \$tableName, unknown \$schemaName, unknown \$referenceName)

Generates SQL to delete a foreign key from a table

protected array _getTableOptions (unknown \$definition)

Generates SQL to add the table creation options

public string createTable (unknown \$tableName, unknown \$schemaName, unknown \$definition)

Generates SQL to create a table in PostgreSQL

public boolean dropTable (unknown \$tableName, unknown \$schemaName, [unknown \$IfExists])

Generates SQL to drop a table

public string createView (unknown \$viewName, unknown \$definition, unknown \$schemaName)

Generates SQL to create a view

public string dropView (unknown \$viewName, unknown \$schemaName, [unknown \$IfExists])

Generates SQL to drop a view

public *string* **tableExists** (*unknown* \$tableName, [*unknown* \$schemaName])

Generates SQL checking for the existence of a schema.table <code>echo dialect->tableExists("posts", "blog")</code>echo dialect->tableExists("posts")

public *string* **viewExists** (*unknown* \$viewName, [*unknown* \$schemaName])

Generates SQL checking for the existence of a schema.view

public *string* **describeColumns** (*unknown* \$table, [*unknown* \$schema])

Generates a SQL describing a table <code>print_r(dialect->describeColumns("posts")) ?>

public *array* **listTables** ([*unknown* \$schemaName])

List all tables in database

```
<?php  
print_r(dialect->listTables("blog")) ?>
```

public *string* **listViews** ([*unknown* \$schemaName])

Generates the SQL to list all views of a schema or user

public *string* **describeIndexes** (*unknown* \$table, [*unknown* \$schema])

Generates SQL to query indexes on a table

public *string* **describeReferences** (*unknown* \$table, [*unknown* \$schema])

Generates SQL to query foreign keys on a table

public *string* **tableOptions** (*unknown* \$table, [*unknown* \$schema])

Generates the SQL to describe the table creation options

public *string* **limit** (*unknown* \$sqlQuery, *unknown* \$number) inherited from Phalcon\Db\Dialect

Generates the SQL for LIMIT clause

```
<?php  
  
$sql = $dialect->limit('SELECT * FROM robots', 10);  
echo $sql; // SELECT * FROM robots LIMIT 10
```

public *string* **forUpdate** (*unknown* \$sqlQuery) inherited from Phalcon\Db\Dialect

Returns a SQL modified with a FOR UPDATE clause

```
<?php  
  
$sql = $dialect->forUpdate('SELECT * FROM robots');  
echo $sql; // SELECT * FROM robots FOR UPDATE
```

public *string* **sharedLock** (*unknown* \$sqlQuery) inherited from Phalcon\Db\Dialect

Returns a SQL modified with a LOCK IN SHARE MODE clause

```
<?php  
  
$sql = $dialect->sharedLock('SELECT * FROM robots');  
echo $sql; // SELECT * FROM robots LOCK IN SHARE MODE
```

final public *string* **getColumnList** (*unknown* \$columnList) inherited from Phalcon\Db\Dialect

Gets a list of columns with escaped identifiers

```
<?php
echo $dialect->getColumnList(array('column1', 'column'));
```

public string getSqlExpression (*unknown* \$expression, [*unknown* \$escapeChar]) inherited from Phalcon\Db\Dialect

Transforms an intermediate representation for a expression into a database system valid expression

final public string getSqlTable (*unknown* \$table, [*unknown* \$escapeChar]) inherited from Phalcon\Db\Dialect

Transform an intermediate representation of a schema/table into a database system valid expression

public string select (*unknown* \$definition) inherited from Phalcon\Db\Dialect

Builds a SELECT statement

public boolean supportsSavepoints () inherited from Phalcon\Db\Dialect

Checks whether the platform supports savepoints

public boolean supportsReleaseSavepoints () inherited from Phalcon\Db\Dialect

Checks whether the platform supports releasing savepoints.

public string createSavepoint (*unknown* \$name) inherited from Phalcon\Db\Dialect

Generate SQL to create a new savepoint

public string releaseSavepoint (*unknown* \$name) inherited from Phalcon\Db\Dialect

Generate SQL to release a savepoint

public string rollbackSavepoint (*unknown* \$name) inherited from Phalcon\Db\Dialect

Generate SQL to rollback a savepoint

2.58.66 Class Phalcon\Db\Dialect\Sqlite

extends abstract class Phalcon\Db\Dialect

implements Phalcon\Db\DialectInterface

Generates database specific SQL for the Sqlite RDBM

Methods

public string getColumnDefinition (*unknown* \$column)

Gets the column name in SQLite

public addColumn (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$column)

Generates SQL to add a column to a table

public string modifyColumn (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$column)

Generates SQL to modify a column in a table

public string dropColumn (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$columnName)

Generates SQL to delete a column from a table

public string addIndex (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$index)

Generates SQL to add an index to a table

public *string* **dropIndex** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$indexName)

Generates SQL to delete an index from a table

public *string* **addPrimaryKey** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$index)

Generates SQL to add the primary key to a table

public *string* **dropPrimaryKey** (*unknown* \$tableName, *unknown* \$schemaName)

Generates SQL to delete primary key from a table

public *string* **addForeignKey** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$reference)

Generates SQL to add an index to a table

public *string* **dropForeignKey** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$referenceName)

Generates SQL to delete a foreign key from a table

protected *array* **_getTableOptions** (*unknown* \$definition)

Generates SQL to add the table creation options

public *string* **createTable** (*unknown* \$tableName, *unknown* \$schemaName, *unknown* \$definition)

Generates SQL to create a table in MySQL

public *string* **dropTable** (*unknown* \$tableName, *unknown* \$schemaName, [*unknown* \$IfExists])

Generates SQL to drop a table

public *string* **createView** (*unknown* \$viewName, *unknown* \$definition, *unknown* \$schemaName)

Generates SQL to create a view

public *string* **dropView** (*unknown* \$viewName, *unknown* \$schemaName, [*unknown* \$IfExists])

Generates SQL to drop a view

public *string* **tableExists** (*unknown* \$tableName, [*unknown* \$schemaName])

Generates SQL checking for the existence of a schema.table

```
<?php
```

```
echo $dialect->tableExists("posts", "blog");
echo $dialect->tableExists("posts");
```

public *string* **viewExists** (*unknown* \$viewName, [*unknown* \$schemaName])

Generates SQL checking for the existence of a schema.view

public *string* **describeColumns** (*unknown* \$table, [*unknown* \$schema])

Generates SQL describing a table

```
<?php
```

```
print_r($dialect->describeColumns("posts"));
```

public *array* **listTables** ([*unknown* \$schemaName])

List all tables in database

```
<?php
```

```
print_r($dialect->listTables("blog"))
```

public array listViews ([*unknown* \$schemaName])

Generates the SQL to list all views of a schema or user

public string describeIndexes (*unknown* \$table, [*unknown* \$schema])

Generates SQL to query indexes on a table

public string describeIndex (*unknown* \$index)

Generates SQL to query indexes detail on a table

public string describeReferences (*unknown* \$table, [*unknown* \$schema])

Generates SQL to query foreign keys on a table

public string tableOptions (*unknown* \$table, [*unknown* \$schema])

Generates the SQL to describe the table creation options

public string limit (*unknown* \$sqlQuery, *unknown* \$number) inherited from Phalcon\Db\Dialect

Generates the SQL for LIMIT clause

```
<?php
$sql = $dialect->limit('SELECT * FROM robots', 10);
echo $sql; // SELECT * FROM robots LIMIT 10
```

public string forUpdate (*unknown* \$sqlQuery) inherited from Phalcon\Db\Dialect

Returns a SQL modified with a FOR UPDATE clause

```
<?php
$sql = $dialect->forUpdate('SELECT * FROM robots');
echo $sql; // SELECT * FROM robots FOR UPDATE
```

public string sharedLock (*unknown* \$sqlQuery) inherited from Phalcon\Db\Dialect

Returns a SQL modified with a LOCK IN SHARE MODE clause

```
<?php
$sql = $dialect->sharedLock('SELECT * FROM robots');
echo $sql; // SELECT * FROM robots LOCK IN SHARE MODE
```

final public string getColumnList (*unknown* \$columnList) inherited from Phalcon\Db\Dialect

Gets a list of columns with escaped identifiers

```
<?php
echo $dialect->getColumnList(array('column1', 'column'));
```

public string getSqlExpression (*unknown* \$expression, [*unknown* \$escapeChar]) inherited from Phalcon\Db\Dialect

Transforms an intermediate representation for a expression into a database system valid expression

final public string getSqlTable (*unknown* \$table, [*unknown* \$escapeChar]) inherited from Phalcon\Db\Dialect

Transform an intermediate representation of a schema/table into a database system valid expression

public string select (*unknown* \$definition) inherited from Phalcon\Db\Dialect

Builds a SELECT statement

public **boolean supportsSavepoints ()** inherited from Phalcon\Db\Dialect
Checks whether the platform supports savepoints

public **boolean supportsReleaseSavepoints ()** inherited from Phalcon\Db\Dialect
Checks whether the platform supports releasing savepoints.

public **string createSavepoint (*unknown \$name*)** inherited from Phalcon\Db\Dialect
Generate SQL to create a new savepoint

public **string releaseSavepoint (*unknown \$name*)** inherited from Phalcon\Db\Dialect
Generate SQL to release a savepoint

public **string rollbackSavepoint (*unknown \$name*)** inherited from Phalcon\Db\Dialect
Generate SQL to rollback a savepoint

2.58.67 Class Phalcon\Db\Exception

extends class Phalcon\Exception

Methods

final private **Exception __clone ()** inherited from Exception
Clone the exception

public **__construct ([*string \$message*], [*int \$code*], [*Exception \$previous*])** inherited from Exception
Exception constructor

final public **string getMessage ()** inherited from Exception
Gets the Exception message

final public **int getCode ()** inherited from Exception
Gets the Exception code

final public **string getFile ()** inherited from Exception
Gets the file in which the exception occurred

final public **int getLine ()** inherited from Exception
Gets the line in which the exception occurred

final public **array getTrace ()** inherited from Exception
Gets the stack trace

final public **Exception getPrevious ()** inherited from Exception
Returns previous Exception

final public **Exception getTraceAsString ()** inherited from Exception
Gets the stack trace as a string

public **string __toString ()** inherited from Exception
String representation of the exception

2.58.68 Class Phalcon\Db\Index

implements Phalcon\Db\IndexInterface

Allows to define indexes to be used on tables. Indexes are a common way to enhance database performance. An index allows the database server to find and retrieve specific rows much faster than it could do without an index

Methods

public getName ()

Index name

public getColumns ()

Index columns

public getType ()

Index type

public __construct (unknown \$name, unknown \$columns, [unknown \$type])

Phalcon\Db\Index constructor

public static __set_state (unknown \$data)

Restore a Phalcon\Db\Index object from export

2.58.69 Class Phalcon\Db\Profiler

Instances of Phalcon\Db can generate execution profiles on SQL statements sent to the relational database. Profiled information includes execution time in miliseconds. This helps you to identify bottlenecks in your applications.

```
<?php

$profiler = new \Phalcon\Db\Profiler();

//Set the connection profiler
$connection->setProfiler($profiler);

$sql = "SELECT buyer_name, quantity, product_name
FROM buyers LEFT JOIN products ON
buyers.pid=products.id";

//Execute a SQL statement
$connection->query($sql);

//Get the last profile in the profiler
$profile = $profiler->getLastProfile();

echo "SQL Statement: ", $profile->getSQLStatement(), "\n";
echo "Start Time: ", $profile->getInitialTime(), "\n";
echo "Final Time: ", $profile->getFinalTime(), "\n";
echo "Total Elapsed Time: ", $profile->getTotalElapsedSeconds(), "\n";
```

Methods

public `Phalcon\Db\Profiler` **startProfile** (*unknown* \$sqlStatement, [*unknown* \$sqlVariables], [*unknown* \$sqlBindTypes])

Starts the profile of a SQL sentence

public `Phalcon\Db\Profiler` **stopProfile** ()

Stops the active profile

public *integer* **getNumberTotalStatements** ()

Returns the total number of SQL statements processed

public *double* **getTotalElapsedSeconds** ()

Returns the total time in seconds spent by the profiles

public `Phalcon\Db\Profiler\Item` [] **getProfiles** ()

Returns all the processed profiles

public `Phalcon\Db\Profiler` **reset** ()

Resets the profiler, cleaning up all the profiles

public `Phalcon\Db\Profiler\Item` **getLastProfile** ()

Returns the last profile executed in the profiler

2.58.70 Class Phalcon\Db\Profiler\Item

This class identifies each profile in a `Phalcon\Db\Profiler`

Methods

public **setSqlStatement** (*unknown* \$sqlStatement)

SQL statement related to the profile

public **getSqlStatement** ()

SQL statement related to the profile

public **setSqlVariables** (*unknown* \$sqlVariables)

SQL variables related to the profile

public **getSqlVariables** ()

SQL variables related to the profile

public **setSqlBindTypes** (*unknown* \$sqlBindTypes)

SQL bind types related to the profile

public **getSqlBindTypes** ()

SQL bind types related to the profile

public **setInitialTime** (*unknown* \$initialTime)

Timestamp when the profile started

public **getInitialTime** ()

Timestamp when the profile started

public setFinalTime (unknown \$finalTime)

Timestamp when the profile ended

public getFinalTime ()

Timestamp when the profile ended

public double getTotalElapsedSeconds ()

Returns the total time in seconds spent by the profile

2.58.71 Class Phalcon\Db\RawValue

This class allows to insert/update raw data without quoting or formating. The next example shows how to use the MySQL now() function as a field value.

```
<?php

$subscriber = new Subscribers();
$subscriber->email = 'andres@phalconphp.com';
$subscriber->createdAt = new \Phalcon\Db\RawValue('now()');
$subscriber->save();
```

Methods

public getValue ()

Raw value without quoting or formating

public __toString ()

Raw value without quoting or formating

public __construct (unknown \$value)

Phalcon\Db\RawValue constructor

2.58.72 Class Phalcon\Db\Reference

implements Phalcon\Db\ReferenceInterface

Allows to define reference constraints on tables

```
<?php

$reference = new \Phalcon\Db\Reference("field_fk", array(
    'referencedSchema' => "invoicing",
    'referencedTable' => "products",
    'columns' => array("product_type", "product_code"),
    'referencedColumns' => array("type", "code")
));
```

Methods

```
public getName ()  
Constraint name  
public getSchemaName ()  
...  
public getReferencedSchema ()  
...  
public getReferencedTable ()  
Referenced Table  
public getColumns ()  
Local reference columns  
public getReferencedColumns ()  
Referenced Columns  
public getonDelete ()  
ON DELETE  
public getOnUpdate ()  
ON UPDATE  
public __construct (unknown $name, unknown $definition)  
Phalcon\Db\Reference constructor  
public static Phalcon\Db\Reference __set_state (unknown $data)  
Restore a Phalcon\Db\Reference object from export
```

2.58.73 Class Phalcon\Db\Result\Pdo

implements Phalcon\Db\ResultInterface

Encapsulates the resultset internals

```
<?php  
  
$result = $connection->query("SELECT * FROM robots ORDER BY name");  
$result->setFetchMode(Phalcon\Db::FETCH_NUM);  
while ($robot = $result->fetchArray()) {  
    print_r($robot);  
}
```

Methods

```
public __construct (unknown $connection, unknown $result, [unknown $sqlStatement], [unknown $bindParams], [unknown $bindTypes])  
Phalcon\Db\Result\Pdo constructor  
public boolean execute ()
```

Allows to execute the statement again. Some database systems don't support scrollable cursors, So, as cursors are forward only, we need to execute the cursor again to fetch rows from the begining

public mixed fetch ()

Fetches an array/object of strings that corresponds to the fetched row, or FALSE if there are no more rows. This method is affected by the active fetch flag set using Phalcon\Db\Result\Pdo::setFetchMode

```
<?php

$result = $connection->query("SELECT * FROM robots ORDER BY name");
$result->setFetchMode(Phalcon\Db::FETCH_OBJ);
while ($robot = $result->fetch()) {
    echo $robot->name;
}
```

public mixed fetchArray ()

Returns an array of strings that corresponds to the fetched row, or FALSE if there are no more rows. This method is affected by the active fetch flag set using Phalcon\Db\Result\Pdo::setFetchMode

```
<?php

$result = $connection->query("SELECT * FROM robots ORDER BY name");
$result->setFetchMode(Phalcon\Db::FETCH_NUM);
while ($robot = $result->fetchArray()) {
    print_r($robot);
}
```

public array fetchAll ()

Returns an array of arrays containing all the records in the result This method is affected by the active fetch flag set using Phalcon\Db\Result\Pdo::setFetchMode

```
<?php

$result = $connection->query("SELECT * FROM robots ORDER BY name");
$robots = $result->fetchAll();
```

public int numRows ()

Gets number of rows returned by a resulset

```
<?php

$result = $connection->query("SELECT * FROM robots ORDER BY name");
echo 'There are ', $result->numRows(), ' rows in the resulset';
```

public dataSeek (*unknown* \$number)

Moves internal resulset cursor to another position letting us to fetch a certain row

```
<?php

$result = $connection->query("SELECT * FROM robots ORDER BY name");
$result->dataSeek(2); // Move to third row on result
$row = $result->fetch(); // Fetch third row
```

public setFetchMode (*unknown* \$fetchMode)

Changes the fetching mode affecting Phalcon\Db\Result\Pdo::fetch()

```
<?php

//Return array with integer indexes
$result->setFetchMode(Phalcon\Db::FETCH_NUM);

//Return associative array without integer indexes
$result->setFetchMode(Phalcon\Db::FETCH_ASSOC);

//Return associative array together with integer indexes
$result->setFetchMode(Phalcon\Db::FETCH_BOTH);

//Return an object
$result->setFetchMode(Phalcon\Db::FETCH_OBJ);
```

public *PDOStatement* **getInternalResult** ()

Gets the internal PDO result object

2.58.74 Class Phalcon\Debug

Provides debug capabilities to Phalcon applications

Methods

public *Phalcon\Debug* **setUri** (*unknown* \$uri)

Change the base URI for static resources

public *Phalcon\Debug* **setShowBackTrace** (*unknown* \$showBackTrace)

Sets if files the exception's backtrace must be showed

public *Phalcon\Debug* **setShowFiles** (*unknown* \$showFiles)

Set if files part of the backtrace must be shown in the output

public *Phalcon\Debug* **setShowFileFragment** (*unknown* \$showFileFragment)

Sets if files must be completely opened and showed in the output or just the fragment related to the exception

public *Phalcon\Debug* **listen** ([*unknown* \$exceptions], [*unknown* \$lowSeverity])

Listen for uncaught exceptions and unsilent notices or warnings

public *Phalcon\Debug* **listenExceptions** ()

Listen for uncaught exceptions

public *Phalcon\Debug* **listenLowSeverity** ()

Listen for unsilent notices or warnings

public **halt** ()

Halts the request showing a backtrace

public *Phalcon\Debug* **debugVar** (*unknown* \$varz, [*unknown* \$key])

Adds a variable to the debug output

public *Phalcon\Debug* **clearVars** ()

Clears are variables added previously

protected *string* **_escapeString** (*unknown* \$value)
 Escapes a string with htmlentities

protected *string* **_getArrayDump** (*unknown* \$argument, [*unknown* \$n])
 Produces a recursive representation of an array

protected *string* **_getVarDump** (*unknown* \$variable)
 Produces an string representation of a variable

public *string* **getMajorVersion** ()
 Returns the major framework's version

public *string* **getVersion** ()
 Generates a link to the current version documentation

public *string* **getCssSources** ()
 Returns the css sources

public *string* **getJsSources** ()
 Returns the javascript sources

final protected **showTraceItem** (*unknown* \$n, *unknown* \$trace)
 Shows a backtrace item

public *boolean* **onUncaughtException** (*unknown* \$exception)
 Handles uncaught exceptions

2.58.75 Class Phalcon\Debug\Dump

Dumps information about a variable(s)

```
<?php
$foo = 123;
echo (new \Phalcon\Debug\Dump())->var($foo, "foo");
```

```
<?php
$foo = "string";
$bar = ["key" => "value"];
$baz = new stdClass();
echo (new \Phalcon\Debug\Dump())->vars($foo, $bar, $baz);
```

Methods

public **getDetailed** ()
 ...

public **setDetailed** (*unknown* \$detailed)
 ...

public **__construct** ([*unknown* \$styles], [*unknown* \$detailed])

Phalcon\Debug\Dump constructor

public string all ()

Alias of vars() method

protected string getStyle (unknown \$type)

Get style for type

public array setStyles ([unknown \$styles])

Set styles for vars type

public string one (unknown \$variable, [unknown \$name])

Alias of var() method

protected string output (unknown \$variable, [unknown \$name], [unknown \$tab])

Prepare an HTML string of information about a single variable.

public string var (unknown \$variable, [unknown \$name])

Returns an HTML string of information about a single variable.

```
<?php
```

```
echo (new \Phalcon\Debug\Dump ())->var ($foo, "foo");
```

public string vars ()

Returns an HTML string of debugging information about any number of variables, each wrapped in a “pre” tag.

```
<?php
```

```
$foo = "string";
$bar = ["key" => "value"];
$baz = new stdClass();
echo (new \Phalcon\Debug\Dump ())->vars ($foo, $bar, $baz);
```

2.58.76 Class Phalcon\Debug\Exception

extends class Phalcon\Exception

Methods

final private Exception __clone () inherited from Exception

Clone the exception

public __construct ([string \$message], [int \$code], [Exception \$previous]) inherited from Exception

Exception constructor

final public string getMessage () inherited from Exception

Gets the Exception message

final public int getCode () inherited from Exception

Gets the Exception code

final public string getFile () inherited from Exception

Gets the file in which the exception occurred

`final public int getLine ()` inherited from `Exception`

Gets the line in which the exception occurred

`final public array getTrace ()` inherited from `Exception`

Gets the stack trace

`final public Exception getPrevious ()` inherited from `Exception`

Returns previous `Exception`

`final public Exception getTraceAsString ()` inherited from `Exception`

Gets the stack trace as a string

`public string __toString ()` inherited from `Exception`

String representation of the exception

2.58.77 Abstract class Phalcon\Dispatcher

`implements Phalcon\DispatcherInterface, Phalcon\Di\InjectionAwareInterface, Phalcon\Events\EventsAwareInterface`

This is the base class for `Phalcon\Mvc\Dispatcher` and `Phalcon\CLI\Dispatcher`. This class can't be instantiated directly, you can use it to create your own dispatchers

Constants

`integer EXCEPTION_NO_DI`

`integer EXCEPTION_CYCLIC_ROUTING`

`integer EXCEPTION_HANDLER_NOT_FOUND`

`integer EXCEPTION_INVALID_HANDLER`

`integer EXCEPTION_INVALID_PARAMS`

`integer EXCEPTION_ACTION_NOT_FOUND`

Methods

`public __construct ()`

Phalcon\Dispatcher constructor

`public setDI (unknown $dependencyInjector)`

Sets the dependency injector

`public Phalcon\DiInterface getDI ()`

Returns the internal dependency injector

`public setEventsManager (unknown $eventsManager)`

Sets the events manager

`public Phalcon\Events\ManagerInterface getEventsManager ()`

Returns the internal event manager

public `setActionSuffix` (*unknown* \$actionSuffix)

Sets the default action suffix

public `setModuleName` (*unknown* \$moduleName)

Sets the module where the controller is (only informative)

public `string getModuleName` ()

Gets the module where the controller class is

public `setNamespaceName` (*unknown* \$namespaceName)

Sets the namespace where the controller class is

public `string getNamespaceName` ()

Gets a namespace to be prepended to the current handler name

public `setDefaultNamespace` (*unknown* \$namespaceName)

Sets the default namespace

public `string getDefaultNamespace` ()

Returns the default namespace

public `setDefaultAction` (*unknown* \$actionName)

Sets the default action name

public `setActionName` (*unknown* \$actionName)

Sets the action name to be dispatched

public `string getActionName` ()

Gets the latest dispatched action name

public `setParams` (*unknown* \$params)

Sets action params to be dispatched

public `array getParams` ()

Gets action params

public `setParam` (*unknown* \$param, *unknown* \$value)

Set a param by its name or numeric index

public `mixed getParam` (*unknown* \$param, [*unknown* \$filters], [*unknown* \$defaultValue])

Gets a param by its name or numeric index

public `string getActiveMethod` ()

Returns the current method to be/executed in the dispatcher

public `boolean isFinished` ()

Checks if the dispatch loop is finished or has more pendent controllers/tasks to dispatch

public `setReturnValue` (*unknown* \$value)

Sets the latest returned value by an action manually

public `mixed getReturnValue` ()

Returns value returned by the lastest dispatched action

public object dispatch ()

Dispatches a handle action taking into account the routing parameters

public forward (unknown \$forward)

Forwards the execution flow to another controller/action Dispatchers are unique per module. Forwarding between modules is not allowed

```
<?php
```

```
$this->dispatcher->forward(array("controller" => "posts", "action" => "index"));
```

public boolean wasForwarded ()

Check if the current executed action was forwarded by another one

2.58.78 Class Phalcon\Escaper

implements Phalcon\EscaperInterface

Escapes different kinds of text securing them. By using this component you may prevent XSS attacks. This component only works with UTF-8. The PREG extension needs to be compiled with UTF-8 support.

```
<?php
```

```
$escaper = new \Phalcon\Escaper();
$escaped = $escaper->escapeCss("font-family: <Verdana>");
echo $escaped; // font\2D family\3A \20 \3C Verdana\3E
```

Methods

public setEncoding (unknown \$encoding)

Sets the encoding to be used by the escaper

```
<?php
```

```
$escaper->setEncoding('utf-8');
```

public string getEncoding ()

Returns the internal encoding used by the escaper

public setHtmlQuoteType (unknown \$quoteType)

Sets the HTML quoting type for htmlspecialchars

```
<?php
```

```
$escaper->setHtmlQuoteType(ENT_XHTML);
```

public string/null detectEncoding (unknown \$str)

Detect the character encoding of a string to be handled by an encoder Special-handling for chr(172) and chr(128) to chr(159) which fail to be detected by mb_detect_encoding()

public string normalizeEncoding (unknown \$str)

Utility to normalize a string's encoding to UTF-32.

public *string* **escapeHtml** (*unknown* \$text)

Escapes a HTML string. Internally uses htmlspecialchars

public *string* **escapeHtmlAttr** (*unknown* \$attribute)

Escapes a HTML attribute string

public *string* **escapeCss** (*unknown* \$css)

Escape CSS strings by replacing non-alphanumeric chars by their hexadecimal escaped representation

public *string* **escapeJs** (*unknown* \$js)

Escape javascript strings by replacing non-alphanumeric chars by their hexadecimal escaped representation

public *string* **escapeUrl** (*unknown* \$url)

Escapes a URL. Internally uses rawurlencode

2.58.79 Class Phalcon\Escaper\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception

Gets the stack trace as a string

public *string* **__toString** () inherited from Exception

String representation of the exception

2.58.80 Class Phalcon\Events\Event

This class offers contextual information of a fired event in the EventsManager

Methods

public **setType** (*unknown* \$type)

Event type

public **getType** ()

Event type

public **getSource** ()

Event source

public **setData** (*unknown* \$data)

Event data

public **getData** ()

Event data

public **getCancelable** ()

Is event cancelable?

public **__construct** (*unknown* \$type, *unknown* \$source, [*unknown* \$data], [*unknown* \$cancelable])

Phalcon\Events\Event constructor

public **stop** ()

Stops the event preventing propagation

public *boolean* **isStopped** ()

Check whether the event is currently stopped

2.58.81 Class Phalcon\Events\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception
Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception
Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception
Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception
Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception
Gets the stack trace as a string

public *string* **__toString** () inherited from Exception
String representation of the exception

2.58.82 Class Phalcon\Events\Manager

implements Phalcon\Events\ManagerInterface

Phalcon Events Manager, offers an easy way to intercept and manipulate, if needed, the normal flow of operation. With the EventsManager the developer can create hooks or plugins that will offer monitoring of data, manipulation, conditional execution and much more.

Methods

public **attach** (*unknown* \$eventType, *unknown* \$handler, [*unknown* \$priority])
Attach a listener to the events manager

public **detach** (*unknown* \$eventType, *unknown* \$handler)
Detach the listener from the events manager

public **enablePriorities** (*unknown* \$enablePriorities)
Set if priorities are enabled in the EventsManager

public *boolean* **arePrioritiesEnabled** ()
Returns if priorities are enabled

public **collectResponses** (*unknown* \$collect)
Tells the event manager if it needs to collect all the responses returned by every registered listener in a single fire

public **isCollecting** ()
Check if the events manager is collecting all the responses returned by every registered listener in a single fire

public *array* **getResponses** ()
Returns all the responses returned by every handler executed by the last ‘fire’ executed

public **detachAll** ([*unknown* \$type])
Removes all events from the EventsManager

public **detachAll** ([*unknown \$type*])

Alias of `detachAll`

final public *mixed fireQueue* (*unknown \$queue, unknown \$event*)

Internal handler to call a queue of events

public *mixed fire* (*unknown \$eventType, unknown \$source, [unknown \$data], [unknown \$cancelable]*)

Fires an event in the events manager causing that active listeners be notified about it

```
<?php
```

```
$eventsManager->fire ('db', $connection);
```

public *boolean hasListeners* (*unknown \$type*)

Check whether certain type of event has listeners

public *array getListeners* (*unknown \$type*)

Returns all the attached listeners of a certain type

2.58.83 Class Phalcon\Exception

extends Exception

Methods

final private *Exception __clone* () inherited from `Exception`

Clone the exception

public **__construct** ([*string \$message*], [*int \$code*], [*Exception \$previous*]) inherited from `Exception`

Exception constructor

final public *string getMessage* () inherited from `Exception`

Gets the Exception message

final public *int getCode* () inherited from `Exception`

Gets the Exception code

final public *string getFile* () inherited from `Exception`

Gets the file in which the exception occurred

final public *int getLine* () inherited from `Exception`

Gets the line in which the exception occurred

final public *array getTrace* () inherited from `Exception`

Gets the stack trace

final public *Exception getPrevious* () inherited from `Exception`

Returns previous Exception

final public *Exception getTraceAsString* () inherited from `Exception`

Gets the stack trace as a string

public *string* **__toString()** inherited from Exception
String representation of the exception

2.58.84 Class Phalcon\Filter

implements Phalcon\FilterInterface

The Phalcon\Filter component provides a set of commonly needed data filters. It provides object oriented wrappers to the php filter extension. Also allows the developer to define his/her own filters

```
<?php

$filter = new \Phalcon\Filter();
$filter->sanitize("some(one)@exa\\mple.com", "email"); // returns "someone@example.com"
$filter->sanitize("hello<<", "string"); // returns "hello"
$filter->sanitize("!100a019", "int"); // returns "100019"
$filter->sanitize("!100a019.01a", "float"); // returns "100019.01"
```

Methods

public Phalcon\Filter **add** (*unknown* \$name, *unknown* \$handler)

Adds a user-defined filter

public *mixed* **sanitize** (*unknown* \$value, *unknown* \$filters, [*unknown* \$noRecursive])

Sanitizes a value with a specified single or set of filters

protected *mixed* **_sanitize** (*mixed* \$value, *string* \$filter)

Internal sanitize wrapper to filter_var

public *object*[] **getFilters** ()

Return the user-defined filters in the instance

2.58.85 Class Phalcon\Filter\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

`final public int getLine ()` inherited from `Exception`

Gets the line in which the exception occurred

`final public array getTrace ()` inherited from `Exception`

Gets the stack trace

`final public Exception getPrevious ()` inherited from `Exception`

Returns previous `Exception`

`final public Exception getTraceAsString ()` inherited from `Exception`

Gets the stack trace as a string

`public string __toString ()` inherited from `Exception`

String representation of the exception

2.58.86 Abstract class Phalcon\Flash

Shows HTML notifications related to different circumstances. Classes can be stylized using CSS

```
<?php
$flash->success("The record was successfully deleted");
$flash->error("Cannot open the file");
```

Methods

`public __construct ([unknown $cssClasses])`

Phalcon\Flash constructor

`public Phalcon\FlashInterface setImplicitFlush (unknown $implicitFlush)`

Set whether the output must be implicitly flushed to the output or returned as string

`public Phalcon\FlashInterface setAutomaticHtml (unknown $automaticHtml)`

Set if the output must be implicitly formatted with HTML

`public Phalcon\FlashInterface setCssClasses (unknown $cssClasses)`

Set an array with CSS classes to format the messages

`public string error (unknown $message)`

Shows a HTML error message

```
<?php
```

```
$flash->error('This is an error');
```

`public string notice (unknown $message)`

Shows a HTML notice/information message

```
<?php
```

```
$flash->notice('This is an information');
```

public *string* **success** (*unknown* \$message)

Shows a HTML success message

```
<?php  
    $flash->success('The process was finished successfully');
```

public *string* **warning** (*unknown* \$message)

Shows a HTML warning message

```
<?php  
    $flash->warning('Hey, this is important');
```

public **outputMessage** (*unknown* \$type, *unknown* \$message)

Outputs a message formatting it with HTML

```
<?php  
    $flash->outputMessage('error', message);
```

2.58.87 Class Phalcon\Flash\Direct

extends abstract class Phalcon\Flash

implements Phalcon\FlashInterface

This is a variant of the Phalcon\Flash that immediately outputs any message passed to it

Methods

public *string* **message** (*unknown* \$type, *unknown* \$message)

Outputs a message

public **__construct** ([*unknown* \$cssClasses]) inherited from Phalcon\Flash

Phalcon\Flash constructor

public Phalcon\FlashInterface **setImplicitFlush** (*unknown* \$implicitFlush) inherited from Phalcon\Flash

Set whether the output must be implicitly flushed to the output or returned as string

public Phalcon\FlashInterface **setAutomaticHtml** (*unknown* \$automaticHtml) inherited from Phalcon\Flash

Set if the output must be implicitly formatted with HTML

public Phalcon\FlashInterface **setCssClasses** (*unknown* \$cssClasses) inherited from Phalcon\Flash

Set an array with CSS classes to format the messages

public *string* **error** (*unknown* \$message) inherited from Phalcon\Flash

Shows a HTML error message

```
<?php  
    $flash->error('This is an error');
```

public *string* **notice** (*unknown* \$message) inherited from Phalcon\Flash

Shows a HTML notice/information message

```
<?php
$flash->notice('This is an information');
```

public *string* **success** (*unknown* \$message) inherited from Phalcon\Flash

Shows a HTML success message

```
<?php
$flash->success('The process was finished successfully');
```

public *string* **warning** (*unknown* \$message) inherited from Phalcon\Flash

Shows a HTML warning message

```
<?php
$flash->warning('Hey, this is important');
```

public **outputMessage** (*unknown* \$type, *unknown* \$message) inherited from Phalcon\Flash

Outputs a message formatting it with HTML

```
<?php
$flash->outputMessage('error', message);
```

2.58.88 Class Phalcon\Flash\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from *Exception*

Returns previous *Exception*

final public *Exception* **getTraceAsString** () inherited from *Exception*

Gets the stack trace as a string

public *string* **_toString** () inherited from *Exception*

String representation of the exception

2.58.89 Class Phalcon\Flash\Session

extends abstract class *Phalcon\Flash*

implements *Phalcon\FlashInterface*, *Phalcon\Di\InjectionAwareInterface*

Temporarily stores the messages in session, then messages can be printed in the next request

Methods

public **setDI** (*unknown* \$dependencyInjector)

Sets the dependency injector

public *Phalcon\DiInterface* **getDI** ()

Returns the internal dependency injector

protected *array* **_getSessionMessages** (*unknown* \$remove)

Returns the messages stored in session

protected **_setSessionMessages** (*unknown* \$messages)

Stores the messages in session

public **message** (*unknown* \$type, *unknown* \$message)

Adds a message to the session flasher

public *boolean* **has** ([*unknown* \$type])

Checks whether there are messages

public *array* **getMessages** ([*unknown* \$type], [*unknown* \$remove])

Returns the messages in the session flasher

public **output** ([*unknown* \$remove])

Prints the messages in the session flasher

public **clear** ()

...

public **__construct** ([*unknown* \$cssClasses]) inherited from *Phalcon\Flash*

Phalcon\Flash constructor

public *Phalcon\FlashInterface* **setImplicitFlush** (*unknown* \$implicitFlush) inherited from *Phalcon\Flash*

Set whether the output must be implicitly flushed to the output or returned as string

public `Phalcon\FlashInterface` **setAutomaticHtml** (*unknown* \$automaticHtml) inherited from `Phalcon\Flash`

Set if the output must be implicitly formatted with HTML

public `Phalcon\FlashInterface` **setCssClasses** (*unknown* \$cssClasses) inherited from `Phalcon\Flash`

Set an array with CSS classes to format the messages

public `string` **error** (*unknown* \$message) inherited from `Phalcon\Flash`

Shows a HTML error message

```
<?php
$flash->error('This is an error');
```

public `string` **notice** (*unknown* \$message) inherited from `Phalcon\Flash`

Shows a HTML notice/information message

```
<?php
$flash->notice('This is an information');
```

public `string` **success** (*unknown* \$message) inherited from `Phalcon\Flash`

Shows a HTML success message

```
<?php
$flash->success('The process was finished successfully');
```

public `string` **warning** (*unknown* \$message) inherited from `Phalcon\Flash`

Shows a HTML warning message

```
<?php
$flash->warning('Hey, this is important');
```

public `outputMessage` (*unknown* \$type, *unknown* \$message) inherited from `Phalcon\Flash`

Outputs a message formatting it with HTML

```
<?php
$flash->outputMessage('error', message);
```

2.58.90 Abstract class Phalcon\Forms\Element

implements `Phalcon\Forms\ElementInterface`

This is a base class for form elements

Methods

public `__construct` (*unknown* \$name, [*unknown* \$attributes])

Phalcon\Forms\Element constructor

public `Phalcon\Forms\ElementInterface` **setForm** (*unknown* \$form)

Sets the parent form to the element

public `Phalcon\Forms\ElementInterface` **getForm** ()

Returns the parent form to the element

public `Phalcon\Forms\ElementInterface` **setName** (*unknown* \$name)

Sets the element name

public *string* **getName** ()

Returns the element name

public `Phalcon\Forms\ElementInterface` **setFilters** (*unknown* \$filters)

Sets the element filters

public `Phalcon\Forms\ElementInterface` **addFilter** (*unknown* \$filter)

Adds a filter to current list of filters

public *mixed* **getFilters** ()

Returns the element filters

public `Phalcon\Forms\ElementInterface` **addValidators** (*unknown* \$validators, [*unknown* \$merge])

Adds a group of validators

public `Phalcon\Forms\ElementInterface` **addValidator** (*unknown* \$validator)

Adds a validator to the element

public `Phalcon\Validation\ValidatorInterface` [] **getValidators** ()

Returns the validators registered for the element

public *array* **prepareAttributes** ([*unknown* \$attributes], [*unknown* \$useChecked])

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

public `Phalcon\Forms\ElementInterface` **setAttribute** (*unknown* \$attribute, *unknown* \$value)

Sets a default attribute for the element

public *mixed* **getAttribute** (*unknown* \$attribute, [*unknown* \$defaultValue])

Returns the value of an attribute if present

public `Phalcon\Forms\ElementInterface` **setAttributes** (*unknown* \$attributes)

Sets default attributes for the element

public *array* **getAttributes** ()

Returns the default attributes for the element

public `Phalcon\Forms\ElementInterface` **setUserOption** (*unknown* \$option, *unknown* \$value)

Sets an option for the element

public *mixed* **getUserOption** (*unknown* \$option, [*unknown* \$defaultValue])

Returns the value of an option if present

public `Phalcon\Forms\ElementInterface` **setUserOptions** (*unknown* \$options)

Sets options for the element

public *array* **getUserOptions** ()

Returns the options for the element

`public Phalcon\Forms\ElementInterface setLabel (unknown $label)`

Sets the element label

`public string getLabel ()`

Returns the element label

`public string label ([unknown $attributes])`

Generate the HTML to label the element

`public Phalcon\Forms\ElementInterface setDefault (unknown $value)`

Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

`public mixed getDefault ()`

Returns the default value assigned to the element

`public mixed getValue ()`

Returns the element value

`public Phalcon\Validation\Message\Group getMessages ()`

Returns the messages that belongs to the element The element needs to be attached to a form

`public boolean hasMessages ()`

Checks whether there are messages attached to the element

`public Phalcon\Forms\ElementInterface setMessages (unknown $group)`

Sets the validation messages related to the element

`public Phalcon\Forms\ElementInterface appendMessage (unknown $message)`

Appends a message to the internal message list

`public Phalcon\Forms\Element clear ()`

Clears every element in the form to its default value

`public string __toString ()`

Magic method __toString renders the widget without attributes

`abstract public render ([unknown $attributes])` inherited from Phalcon\Forms\ElementInterface

...

2.58.91 Class Phalcon\Forms\Element\Check

extends abstract class Phalcon\Forms\Element

implements Phalcon\Forms\ElementInterface

Component INPUT[type=check] for forms

Methods

`public string render ([unknown $attributes])`

Renders the element widget returning html

`public __construct (unknown $name, [unknown $attributes])` inherited from Phalcon\Forms\Element

Phalcon\Forms\Element constructor

`public Phalcon\Forms\ElementInterface setForm (unknown $form)` inherited from Phalcon\Forms\Element

Sets the parent form to the element

`public Phalcon\Forms\ElementInterface getForm ()` inherited from Phalcon\Forms\Element

Returns the parent form to the element

`public Phalcon\Forms\ElementInterface setName (unknown $name)` inherited from Phalcon\Forms\Element

Sets the element name

`public string getName ()` inherited from Phalcon\Forms\Element

Returns the element name

`public Phalcon\Forms\ElementInterface setFilters (unknown $filters)` inherited from Phalcon\Forms\Element

Sets the element filters

`public Phalcon\Forms\ElementInterface addFilter (unknown $filter)` inherited from Phalcon\Forms\Element

Adds a filter to current list of filters

`public mixed getFilters ()` inherited from Phalcon\Forms\Element

Returns the element filters

`public Phalcon\Forms\ElementInterface addValidators (unknown $validators, [unknown $merge])` inherited from Phalcon\Forms\Element

Adds a group of validators

`public Phalcon\Forms\ElementInterface addValidator (unknown $validator)` inherited from Phalcon\Forms\Element

Adds a validator to the element

`public Phalcon\Validation\ValidatorInterface [] getValidators ()` inherited from Phalcon\Forms\Element

Returns the validators registered for the element

`public array prepareAttributes ([unknown $attributes], [unknown $useChecked])` inherited from Phalcon\Forms\Element

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

`public Phalcon\Forms\ElementInterface setAttribute (unknown $attribute, unknown $value)` inherited from Phalcon\Forms\Element

Sets a default attribute for the element

`public mixed getAttribute (unknown $attribute, [unknown $defaultValue])` inherited from Phalcon\Forms\Element

Returns the value of an attribute if present

`public Phalcon\Forms\ElementInterface setAttributes (unknown $attributes)` inherited from Phalcon\Forms\Element

Sets default attributes for the element

`public array getAttributes ()` inherited from Phalcon\Forms\Element

Returns the default attributes for the element

public [Phalcon\Forms\ElementInterface](#) **setUserOption** (*unknown* \$option, *unknown* \$value) inherited from Phalcon\Forms\Element

Sets an option for the element

public *mixed* **getUserOption** (*unknown* \$option, [*unknown* \$defaultValue]) inherited from Phalcon\Forms\Element

Returns the value of an option if present

public [Phalcon\Forms\ElementInterface](#) **setUserOptions** (*unknown* \$options) inherited from Phalcon\Forms\Element

Sets options for the element

public *array* **getUserOptions** () inherited from Phalcon\Forms\Element

Returns the options for the element

public [Phalcon\Forms\ElementInterface](#) **setLabel** (*unknown* \$label) inherited from Phalcon\Forms\Element

Sets the element label

public *string* **getLabel** () inherited from Phalcon\Forms\Element

Returns the element label

public *string* **label** ([*unknown* \$attributes]) inherited from Phalcon\Forms\Element

Generate the HTML to label the element

public [Phalcon\Forms\ElementInterface](#) **setDefault** (*unknown* \$value) inherited from Phalcon\Forms\Element

Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

public *mixed* **getDefault** () inherited from Phalcon\Forms\Element

Returns the default value assigned to the element

public *mixed* **getValue** () inherited from Phalcon\Forms\Element

Returns the element value

public [Phalcon\Validation\Message\Group](#) **getMessages** () inherited from Phalcon\Forms\Element

Returns the messages that belongs to the element The element needs to be attached to a form

public *boolean* **hasMessages** () inherited from Phalcon\Forms\Element

Checks whether there are messages attached to the element

public [Phalcon\Forms\ElementInterface](#) **setMessages** (*unknown* \$group) inherited from Phalcon\Forms\Element

Sets the validation messages related to the element

public [Phalcon\Forms\ElementInterface](#) **appendMessage** (*unknown* \$message) inherited from Phalcon\Forms\Element

Appends a message to the internal message list

public [Phalcon\Forms\Element](#) **clear** () inherited from Phalcon\Forms\Element

Clears every element in the form to its default value

public *string* **__toString** () inherited from Phalcon\Forms\Element

Magic method __toString renders the widget without attributes

2.58.92 Class Phalcon\Forms\Element\Date

extends abstract class [Phalcon\Forms\Element](#)

implements [Phalcon\Forms\ElementInterface](#)

Component INPUT[type=date] for forms

Methods

public string render ([*unknown* \$attributes])

Renders the element widget returning html

public __construct (*unknown* \$name, [*unknown* \$attributes]) inherited from [Phalcon\Forms\Element](#)

Phalcon\Forms\Element constructor

public [Phalcon\Forms\ElementInterface](#) setForm (*unknown* \$form) inherited from [Phalcon\Forms\Element](#)

Sets the parent form to the element

public [Phalcon\Forms\ElementInterface](#) getForm () inherited from [Phalcon\Forms\Element](#)

Returns the parent form to the element

public [Phalcon\Forms\ElementInterface](#) setName (*unknown* \$name) inherited from [Phalcon\Forms\Element](#)

Sets the element name

public string getName () inherited from [Phalcon\Forms\Element](#)

Returns the element name

public [Phalcon\Forms\ElementInterface](#) setFilters (*unknown* \$filters) inherited from [Phalcon\Forms\Element](#)

Sets the element filters

public [Phalcon\Forms\ElementInterface](#) addFilter (*unknown* \$filter) inherited from [Phalcon\Forms\Element](#)

Adds a filter to current list of filters

public *mixed* getFilters () inherited from [Phalcon\Forms\Element](#)

Returns the element filters

public [Phalcon\Forms\ElementInterface](#) addValidators (*unknown* \$validators, [*unknown* \$merge]) inherited from [Phalcon\Forms\Element](#)

Adds a group of validators

public [Phalcon\Forms\ElementInterface](#) addValidator (*unknown* \$validator) inherited from [Phalcon\Forms\Element](#)

Adds a validator to the element

public [Phalcon\Validation\ValidatorInterface](#) [] getValidators () inherited from [Phalcon\Forms\Element](#)

Returns the validators registered for the element

public *array* prepareAttributes ([*unknown* \$attributes], [*unknown* \$useChecked]) inherited from [Phalcon\Forms\Element](#)

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

public [Phalcon\Forms\ElementInterface](#) setAttribute (*unknown* \$attribute, *unknown* \$value) inherited from [Phalcon\Forms\Element](#)

Sets a default attribute for the element

public *mixed* **getAttribute** (*unknown* \$attribute, [*unknown* \$defaultValue]) inherited from Phalcon\Forms\Element
Returns the value of an attribute if present

public Phalcon\Forms\ElementInterface **setAttributes** (*unknown* \$attributes) inherited from Phalcon\Forms\Element
Sets default attributes for the element

public *array* **getAttributes** () inherited from Phalcon\Forms\Element
Returns the default attributes for the element

public Phalcon\Forms\ElementInterface **setUserOption** (*unknown* \$option, *unknown* \$value) inherited from Phalcon\Forms\Element
Sets an option for the element

public *mixed* **getUserOption** (*unknown* \$option, [*unknown* \$defaultValue]) inherited from Phalcon\Forms\Element
Returns the value of an option if present

public Phalcon\Forms\ElementInterface **setUserOptions** (*unknown* \$options) inherited from Phalcon\Forms\Element
Sets options for the element

public *array* **getUserOptions** () inherited from Phalcon\Forms\Element
Returns the options for the element

public Phalcon\Forms\ElementInterface **setLabel** (*unknown* \$label) inherited from Phalcon\Forms\Element
Sets the element label

public *string* **getLabel** () inherited from Phalcon\Forms\Element
Returns the element label

public *string* **label** ([*unknown* \$attributes]) inherited from Phalcon\Forms\Element
Generate the HTML to label the element

public Phalcon\Forms\ElementInterface **setDefault** (*unknown* \$value) inherited from Phalcon\Forms\Element
Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

public *mixed* **getDefault** () inherited from Phalcon\Forms\Element
Returns the default value assigned to the element

public *mixed* **getValue** () inherited from Phalcon\Forms\Element
Returns the element value

public Phalcon\Validation\Message\Group **getMessages** () inherited from Phalcon\Forms\Element
Returns the messages that belongs to the element The element needs to be attached to a form

public *boolean* **hasMessages** () inherited from Phalcon\Forms\Element
Checks whether there are messages attached to the element

public Phalcon\Forms\ElementInterface **setMessages** (*unknown* \$group) inherited from Phalcon\Forms\Element
Sets the validation messages related to the element

public Phalcon\Forms\ElementInterface **appendMessage** (*unknown* \$message) inherited from Phalcon\Forms\Element
Appends a message to the internal message list

public Phalcon\Forms\Element **clear** () inherited from Phalcon\Forms\Element

Clears every element in the form to its default value

public *string* **__toString()** inherited from Phalcon\Forms\Element

Magic method __toString renders the widget without attributes

2.58.93 Class Phalcon\Forms\Element\Email

extends abstract class Phalcon\Forms\Element

implements Phalcon\Forms\ElementInterface

Component INPUT[type=email] for forms

Methods

public *string* **render** ([*unknown* \$attributes])

Renders the element widget returning html

public **__construct** (*unknown* \$name, [*unknown* \$attributes]) inherited from Phalcon\Forms\Element

Phalcon\Forms\Element constructor

public Phalcon\Forms\ElementInterface **setForm** (*unknown* \$form) inherited from Phalcon\Forms\Element

Sets the parent form to the element

public Phalcon\Forms\ElementInterface **getForm** () inherited from Phalcon\Forms\Element

Returns the parent form to the element

public Phalcon\Forms\ElementInterface **setName** (*unknown* \$name) inherited from Phalcon\Forms\Element

Sets the element name

public *string* **getName** () inherited from Phalcon\Forms\Element

Returns the element name

public Phalcon\Forms\ElementInterface **setFilters** (*unknown* \$filters) inherited from Phalcon\Forms\Element

Sets the element filters

public Phalcon\Forms\ElementInterface **addFilter** (*unknown* \$filter) inherited from Phalcon\Forms\Element

Adds a filter to current list of filters

public *mixed* **getFilters** () inherited from Phalcon\Forms\Element

Returns the element filters

public Phalcon\Forms\ElementInterface **addValidators** (*unknown* \$validators, [*unknown* \$merge]) inherited from Phalcon\Forms\Element

Adds a group of validators

public Phalcon\Forms\ElementInterface **addValidator** (*unknown* \$validator) inherited from Phalcon\Forms\Element

Adds a validator to the element

public Phalcon\Validation\ValidatorInterface [] **getValidators** () inherited from Phalcon\Forms\Element

Returns the validators registered for the element

public *array* **prepareAttributes** (*[unknown \$attributes]*, *[unknown \$useChecked]*) inherited from Phalcon\Forms\Element

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

public [Phalcon\Forms\ElementInterface](#) **setAttribute** (*unknown \$attribute*, *unknown \$value*) inherited from Phalcon\Forms\Element

Sets a default attribute for the element

public *mixed* **getAttribute** (*unknown \$attribute*, *[unknown \$defaultValue]*) inherited from Phalcon\Forms\Element

Returns the value of an attribute if present

public [Phalcon\Forms\ElementInterface](#) **setAttributes** (*unknown \$attributes*) inherited from Phalcon\Forms\Element

Sets default attributes for the element

public *array* **getAttributes** () inherited from Phalcon\Forms\Element

Returns the default attributes for the element

public [Phalcon\Forms\ElementInterface](#) **setUserOption** (*unknown \$option*, *unknown \$value*) inherited from Phalcon\Forms\Element

Sets an option for the element

public *mixed* **getUserOption** (*unknown \$option*, *[unknown \$defaultValue]*) inherited from Phalcon\Forms\Element

Returns the value of an option if present

public [Phalcon\Forms\ElementInterface](#) **setUserOptions** (*unknown \$options*) inherited from Phalcon\Forms\Element

Sets options for the element

public *array* **getUserOptions** () inherited from Phalcon\Forms\Element

Returns the options for the element

public [Phalcon\Forms\ElementInterface](#) **setLabel** (*unknown \$label*) inherited from Phalcon\Forms\Element

Sets the element label

public *string* **getLabel** () inherited from Phalcon\Forms\Element

Returns the element label

public *string* **label** (*[unknown \$attributes]*) inherited from Phalcon\Forms\Element

Generate the HTML to label the element

public [Phalcon\Forms\ElementInterface](#) **setDefault** (*unknown \$value*) inherited from Phalcon\Forms\Element

Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

public *mixed* **getDefault** () inherited from Phalcon\Forms\Element

Returns the default value assigned to the element

public *mixed* **getValue** () inherited from Phalcon\Forms\Element

Returns the element value

public [Phalcon\Validation\Message\Group](#) **getMessages** () inherited from Phalcon\Forms\Element

Returns the messages that belongs to the element The element needs to be attached to a form

public *boolean* **hasMessages** () inherited from Phalcon\Forms\Element

Checks whether there are messages attached to the element

public [Phalcon\Forms\ElementInterface](#) **setMessages** (*unknown \$group*) inherited from [Phalcon\Forms\Element](#)

Sets the validation messages related to the element

public [Phalcon\Forms\ElementInterface](#) **appendMessage** (*unknown \$message*) inherited from [Phalcon\Forms\Element](#)

Appends a message to the internal message list

public [Phalcon\Forms\Element](#) **clear** () inherited from [Phalcon\Forms\Element](#)

Clears every element in the form to its default value

public *string* **__toString** () inherited from [Phalcon\Forms\Element](#)

Magic method __toString renders the widget without attributes

2.58.94 Class Phalcon\Forms\Element\File

extends abstract class [Phalcon\Forms\Element](#)

implements [Phalcon\Forms\ElementInterface](#)

Component INPUT[type=file] for forms

Methods

public *string* **render** ([*unknown \$attributes*])

Renders the element widget returning html

public **__construct** (*unknown \$name*, [*unknown \$attributes*]) inherited from [Phalcon\Forms\Element](#)

Phalcon\Forms\Element constructor

public [Phalcon\Forms\ElementInterface](#) **setForm** (*unknown \$form*) inherited from [Phalcon\Forms\Element](#)

Sets the parent form to the element

public [Phalcon\Forms\ElementInterface](#) **getForm** () inherited from [Phalcon\Forms\Element](#)

Returns the parent form to the element

public [Phalcon\Forms\ElementInterface](#) **setName** (*unknown \$name*) inherited from [Phalcon\Forms\Element](#)

Sets the element name

public *string* **getName** () inherited from [Phalcon\Forms\Element](#)

Returns the element name

public [Phalcon\Forms\ElementInterface](#) **setFilters** (*unknown \$filters*) inherited from [Phalcon\Forms\Element](#)

Sets the element filters

public [Phalcon\Forms\ElementInterface](#) **addFilter** (*unknown \$filter*) inherited from [Phalcon\Forms\Element](#)

Adds a filter to current list of filters

public *mixed* **getFilters** () inherited from [Phalcon\Forms\Element](#)

Returns the element filters

public [Phalcon\Forms\ElementInterface](#) **addValidators** (*unknown \$validators*, [*unknown \$merge*]) inherited from [Phalcon\Forms\Element](#)

Adds a group of validators

`public Phalcon\Forms\ElementInterface addValidator (unknown $validator) inherited from Phalcon\Forms\Element`

Adds a validator to the element

`public Phalcon\Validation\ValidatorInterface [] getValidators () inherited from Phalcon\Forms\Element`

Returns the validators registered for the element

`public array prepareAttributes ([unknown $attributes], [unknown $useChecked]) inherited from Phalcon\Forms\Element`

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

`public Phalcon\Forms\ElementInterface setAttribute (unknown $attribute, unknown $value) inherited from Phalcon\Forms\Element`

Sets a default attribute for the element

`public mixed getAttribute (unknown $attribute, [unknown $defaultValue]) inherited from Phalcon\Forms\Element`

Returns the value of an attribute if present

`public Phalcon\Forms\ElementInterface setAttributes (unknown $attributes) inherited from Phalcon\Forms\Element`

Sets default attributes for the element

`public array getAttributes () inherited from Phalcon\Forms\Element`

Returns the default attributes for the element

`public Phalcon\Forms\ElementInterface setUserOption (unknown $option, unknown $value) inherited from Phalcon\Forms\Element`

Sets an option for the element

`public mixed getUserOption (unknown $option, [unknown $defaultValue]) inherited from Phalcon\Forms\Element`

Returns the value of an option if present

`public Phalcon\Forms\ElementInterface setUserOptions (unknown $options) inherited from Phalcon\Forms\Element`

Sets options for the element

`public array getUserOptions () inherited from Phalcon\Forms\Element`

Returns the options for the element

`public Phalcon\Forms\ElementInterface setLabel (unknown $label) inherited from Phalcon\Forms\Element`

Sets the element label

`public string getLabel () inherited from Phalcon\Forms\Element`

Returns the element label

`public string label ([unknown $attributes]) inherited from Phalcon\Forms\Element`

Generate the HTML to label the element

`public Phalcon\Forms\ElementInterface setDefault (unknown $value) inherited from Phalcon\Forms\Element`

Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

`public mixed getDefault () inherited from Phalcon\Forms\Element`

Returns the default value assigned to the element

`public mixed getValue () inherited from Phalcon\Forms\Element`

Returns the element value

`public Phalcon\Validation\Message\Group getMessages ()` inherited from `Phalcon\Forms\Element`

Returns the messages that belongs to the element The element needs to be attached to a form

`public boolean hasMessages ()` inherited from `Phalcon\Forms\Element`

Checks whether there are messages attached to the element

`public Phalcon\Forms\ElementInterface setMessages (unknown $group)` inherited from `Phalcon\Forms\Element`

Sets the validation messages related to the element

`public Phalcon\Forms\ElementInterface appendMessage (unknown $message)` inherited from `Phalcon\Forms\Element`

Appends a message to the internal message list

`public Phalcon\Forms\Element clear ()` inherited from `Phalcon\Forms\Element`

Clears every element in the form to its default value

`public string __toString ()` inherited from `Phalcon\Forms\Element`

Magic method `__toString` renders the widget without attributes

2.58.95 Class `Phalcon\Forms\Element\Hidden`

extends abstract class `Phalcon\Forms\Element`

implements `Phalcon\Forms\ElementInterface`

Component INPUT[type=hidden] for forms

Methods

`public string render ([unknown $attributes])`

Renders the element widget returning html

`public __construct (unknown $name, [unknown $attributes])` inherited from `Phalcon\Forms\Element`

Phalcon\Forms\Element constructor

`public Phalcon\Forms\ElementInterface setForm (unknown $form)` inherited from `Phalcon\Forms\Element`

Sets the parent form to the element

`public Phalcon\Forms\ElementInterface getForm ()` inherited from `Phalcon\Forms\Element`

Returns the parent form to the element

`public Phalcon\Forms\ElementInterface setName (unknown $name)` inherited from `Phalcon\Forms\Element`

Sets the element name

`public string getName ()` inherited from `Phalcon\Forms\Element`

Returns the element name

`public Phalcon\Forms\ElementInterface setFilters (unknown $filters)` inherited from `Phalcon\Forms\Element`

Sets the element filters

`public Phalcon\Forms\ElementInterface addFilter (unknown $filter)` inherited from `Phalcon\Forms\Element`

Adds a filter to current list of filters

public *mixed* **getFilters** () inherited from Phalcon\Forms\Element

Returns the element filters

public [Phalcon\Forms\ElementInterface](#) **addValidators** (*unknown* \$validators, [*unknown* \$merge]) inherited from Phalcon\Forms\Element

Adds a group of validators

public [Phalcon\Forms\ElementInterface](#) **addValidator** (*unknown* \$validator) inherited from Phalcon\Forms\Element

Adds a validator to the element

public [Phalcon\Validation\ValidatorInterface](#) [] **getValidators** () inherited from Phalcon\Forms\Element

Returns the validators registered for the element

public *array* **prepareAttributes** ([*unknown* \$attributes], [*unknown* \$useChecked]) inherited from Phalcon\Forms\Element

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

public [Phalcon\Forms\ElementInterface](#) **setAttribute** (*unknown* \$attribute, *unknown* \$value) inherited from Phalcon\Forms\Element

Sets a default attribute for the element

public *mixed* **getAttribute** (*unknown* \$attribute, [*unknown* \$defaultValue]) inherited from Phalcon\Forms\Element

Returns the value of an attribute if present

public [Phalcon\Forms\ElementInterface](#) **setAttributes** (*unknown* \$attributes) inherited from Phalcon\Forms\Element

Sets default attributes for the element

public *array* **getAttributes** () inherited from Phalcon\Forms\Element

Returns the default attributes for the element

public [Phalcon\Forms\ElementInterface](#) **setUserOption** (*unknown* \$option, *unknown* \$value) inherited from Phalcon\Forms\Element

Sets an option for the element

public *mixed* **getUserOption** (*unknown* \$option, [*unknown* \$defaultValue]) inherited from Phalcon\Forms\Element

Returns the value of an option if present

public [Phalcon\Forms\ElementInterface](#) **setUserOptions** (*unknown* \$options) inherited from Phalcon\Forms\Element

Sets options for the element

public *array* **getUserOptions** () inherited from Phalcon\Forms\Element

Returns the options for the element

public [Phalcon\Forms\ElementInterface](#) **setLabel** (*unknown* \$label) inherited from Phalcon\Forms\Element

Sets the element label

public *string* **getLabel** () inherited from Phalcon\Forms\Element

Returns the element label

public *string* **label** ([*unknown* \$attributes]) inherited from Phalcon\Forms\Element

Generate the HTML to label the element

public [Phalcon\Forms\ElementInterface](#) **setDefault** (*unknown* \$value) inherited from [Phalcon\Forms\Element](#)
Sets a default value in case the form does not use an entity or there is no value available for the element in `_POST`

public *mixed* **getDefault** () inherited from [Phalcon\Forms\Element](#)
Returns the default value assigned to the element

public *mixed* **getValue** () inherited from [Phalcon\Forms\Element](#)
Returns the element value

public [Phalcon\Validation\Message\Group](#) **getMessages** () inherited from [Phalcon\Forms\Element](#)
Returns the messages that belongs to the element The element needs to be attached to a form

public *boolean* **hasMessages** () inherited from [Phalcon\Forms\Element](#)
Checks whether there are messages attached to the element

public [Phalcon\Forms\ElementInterface](#) **setMessages** (*unknown* \$group) inherited from [Phalcon\Forms\Element](#)
Sets the validation messages related to the element

public [Phalcon\Forms\ElementInterface](#) **appendMessage** (*unknown* \$message) inherited from [Phalcon\Forms\Element](#)
Appends a message to the internal message list

public [Phalcon\Forms\Element](#) **clear** () inherited from [Phalcon\Forms\Element](#)
Clears every element in the form to its default value

public *string* **__toString** () inherited from [Phalcon\Forms\Element](#)
Magic method `__toString` renders the widget without attributes

2.58.96 Class Phalcon\Forms\Element\Numeric

extends abstract class [Phalcon\Forms\Element](#)

implements [Phalcon\Forms\ElementInterface](#)

Component INPUT[type=number] for forms

Methods

public *string* **render** ([*array* \$attributes])

Renders the element widget returning html

public **__construct** (*unknown* \$name, [*unknown* \$attributes]) inherited from [Phalcon\Forms\Element](#)

Phalcon\Forms\Element constructor

public [Phalcon\Forms\ElementInterface](#) **setForm** (*unknown* \$form) inherited from [Phalcon\Forms\Element](#)

Sets the parent form to the element

public [Phalcon\Forms\ElementInterface](#) **getForm** () inherited from [Phalcon\Forms\Element](#)

Returns the parent form to the element

public [Phalcon\Forms\ElementInterface](#) **setName** (*unknown* \$name) inherited from [Phalcon\Forms\Element](#)

Sets the element name

public *string* **getName** () inherited from Phalcon\Forms\Element

Returns the element name

public *Phalcon\Forms\ElementInterface* **setFilters** (*unknown* \$filters) inherited from Phalcon\Forms\Element

Sets the element filters

public *Phalcon\Forms\ElementInterface* **addFilter** (*unknown* \$filter) inherited from Phalcon\Forms\Element

Adds a filter to current list of filters

public *mixed* **getFilters** () inherited from Phalcon\Forms\Element

Returns the element filters

public *Phalcon\Forms\ElementInterface* **addValidators** (*unknown* \$validators, [*unknown* \$merge]) inherited from Phalcon\Forms\Element

Adds a group of validators

public *Phalcon\Forms\ElementInterface* **addValidator** (*unknown* \$validator) inherited from Phalcon\Forms\Element

Adds a validator to the element

public *Phalcon\Validation\ValidatorInterface* [] **getValidators** () inherited from Phalcon\Forms\Element

Returns the validators registered for the element

public *array* **prepareAttributes** ([*unknown* \$attributes], [*unknown* \$useChecked]) inherited from Phalcon\Forms\Element

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

public *Phalcon\Forms\ElementInterface* **setAttribute** (*unknown* \$attribute, *unknown* \$value) inherited from Phalcon\Forms\Element

Sets a default attribute for the element

public *mixed* **getAttribute** (*unknown* \$attribute, [*unknown* \$defaultValue]) inherited from Phalcon\Forms\Element

Returns the value of an attribute if present

public *Phalcon\Forms\ElementInterface* **setAttributes** (*unknown* \$attributes) inherited from Phalcon\Forms\Element

Sets default attributes for the element

public *array* **getAttributes** () inherited from Phalcon\Forms\Element

Returns the default attributes for the element

public *Phalcon\Forms\ElementInterface* **setUserOption** (*unknown* \$option, *unknown* \$value) inherited from Phalcon\Forms\Element

Sets an option for the element

public *mixed* **getUserOption** (*unknown* \$option, [*unknown* \$defaultValue]) inherited from Phalcon\Forms\Element

Returns the value of an option if present

public *Phalcon\Forms\ElementInterface* **setUserOptions** (*unknown* \$options) inherited from Phalcon\Forms\Element

Sets options for the element

public *array* **getUserOptions** () inherited from Phalcon\Forms\Element

Returns the options for the element

public *Phalcon\Forms\ElementInterface* **setLabel** (*unknown* \$label) inherited from Phalcon\Forms\Element

Sets the element label

public *string* **getLabel** () inherited from Phalcon\Forms\Element

Returns the element label

public *string* **label** ([*unknown* \$attributes]) inherited from Phalcon\Forms\Element

Generate the HTML to label the element

public Phalcon\Forms\ElementInterface **setDefault** (*unknown* \$value) inherited from Phalcon\Forms\Element

Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

public *mixed* **getDefault** () inherited from Phalcon\Forms\Element

Returns the default value assigned to the element

public *mixed* **getValue** () inherited from Phalcon\Forms\Element

Returns the element value

public Phalcon\Validation\Message\Group **getMessages** () inherited from Phalcon\Forms\Element

Returns the messages that belongs to the element The element needs to be attached to a form

public *boolean* **hasMessages** () inherited from Phalcon\Forms\Element

Checks whether there are messages attached to the element

public Phalcon\Forms\ElementInterface **setMessages** (*unknown* \$group) inherited from Phalcon\Forms\Element

Sets the validation messages related to the element

public Phalcon\Forms\ElementInterface **appendMessage** (*unknown* \$message) inherited from Phalcon\Forms\Element

Appends a message to the internal message list

public Phalcon\Forms\Element **clear** () inherited from Phalcon\Forms\Element

Clears every element in the form to its default value

public *string* **__toString** () inherited from Phalcon\Forms\Element

Magic method __toString renders the widget without attributes

2.58.97 Class Phalcon\Forms\Element>Password

extends abstract class Phalcon\Forms\Element

implements Phalcon\Forms\ElementInterface

Component INPUT[type=password] for forms

Methods

public *string* **render** ([*array* \$attributes])

Renders the element widget returning html

public **__construct** (*unknown* \$name, [*unknown* \$attributes]) inherited from Phalcon\Forms\Element

Phalcon\Forms\Element constructor

public Phalcon\Forms\ElementInterface **setForm** (*unknown* \$form) inherited from Phalcon\Forms\Element

Sets the parent form to the element

public [Phalcon\Forms\ElementInterface](#) **getForm** () inherited from [Phalcon\Forms\Element](#)

Returns the parent form to the element

public [Phalcon\Forms\ElementInterface](#) **setName** (*unknown \$name*) inherited from [Phalcon\Forms\Element](#)

Sets the element name

public *string* **getName** () inherited from [Phalcon\Forms\Element](#)

Returns the element name

public [Phalcon\Forms\ElementInterface](#) **setFilters** (*unknown \$filters*) inherited from [Phalcon\Forms\Element](#)

Sets the element filters

public [Phalcon\Forms\ElementInterface](#) **addFilter** (*unknown \$filter*) inherited from [Phalcon\Forms\Element](#)

Adds a filter to current list of filters

public *mixed* **getFilters** () inherited from [Phalcon\Forms\Element](#)

Returns the element filters

public [Phalcon\Forms\ElementInterface](#) **addValidators** (*unknown \$validators*, [*unknown \$merge*]) inherited from [Phalcon\Forms\Element](#)

Adds a group of validators

public [Phalcon\Forms\ElementInterface](#) **addValidator** (*unknown \$validator*) inherited from [Phalcon\Forms\Element](#)

Adds a validator to the element

public [Phalcon\Validation\ValidatorInterface](#) [] **getValidators** () inherited from [Phalcon\Forms\Element](#)

Returns the validators registered for the element

public *array* **prepareAttributes** ([*unknown \$attributes*], [*unknown \$useChecked*]) inherited from [Phalcon\Forms\Element](#)

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

public [Phalcon\Forms\ElementInterface](#) **setAttribute** (*unknown \$attribute*, *unknown \$value*) inherited from [Phalcon\Forms\Element](#)

Sets a default attribute for the element

public *mixed* **getAttribute** (*unknown \$attribute*, [*unknown \$defaultValue*]) inherited from [Phalcon\Forms\Element](#)

Returns the value of an attribute if present

public [Phalcon\Forms\ElementInterface](#) **setAttributes** (*unknown \$attributes*) inherited from [Phalcon\Forms\Element](#)

Sets default attributes for the element

public *array* **getAttributes** () inherited from [Phalcon\Forms\Element](#)

Returns the default attributes for the element

public [Phalcon\Forms\ElementInterface](#) **setUserOption** (*unknown \$option*, *unknown \$value*) inherited from [Phalcon\Forms\Element](#)

Sets an option for the element

public *mixed* **getUserOption** (*unknown \$option*, [*unknown \$defaultValue*]) inherited from [Phalcon\Forms\Element](#)

Returns the value of an option if present

public [Phalcon\Forms\ElementInterface](#) **setUserOptions** (*unknown* \$options) inherited from [Phalcon\Forms\Element](#)
Sets options for the element

public *array* **getUserOptions** () inherited from [Phalcon\Forms\Element](#)
Returns the options for the element

public [Phalcon\Forms\ElementInterface](#) **setLabel** (*unknown* \$label) inherited from [Phalcon\Forms\Element](#)
Sets the element label

public *string* **getLabel** () inherited from [Phalcon\Forms\Element](#)
Returns the element label

public *string* **label** ([*unknown* \$attributes]) inherited from [Phalcon\Forms\Element](#)
Generate the HTML to label the element

public [Phalcon\Forms\ElementInterface](#) **setDefault** (*unknown* \$value) inherited from [Phalcon\Forms\Element](#)
Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

public *mixed* **getDefault** () inherited from [Phalcon\Forms\Element](#)
Returns the default value assigned to the element

public *mixed* **getValue** () inherited from [Phalcon\Forms\Element](#)
Returns the element value

public [Phalcon\Validation\Message\Group](#) **getMessages** () inherited from [Phalcon\Forms\Element](#)
Returns the messages that belongs to the element The element needs to be attached to a form

public *boolean* **hasMessages** () inherited from [Phalcon\Forms\Element](#)
Checks whether there are messages attached to the element

public [Phalcon\Forms\ElementInterface](#) **setMessages** (*unknown* \$group) inherited from [Phalcon\Forms\Element](#)
Sets the validation messages related to the element

public [Phalcon\Forms\ElementInterface](#) **appendMessage** (*unknown* \$message) inherited from [Phalcon\Forms\Element](#)
Appends a message to the internal message list

public [Phalcon\Forms\Element](#) **clear** () inherited from [Phalcon\Forms\Element](#)
Clears every element in the form to its default value

public *string* **__toString** () inherited from [Phalcon\Forms\Element](#)
Magic method __toString renders the widget without attributes

2.58.98 Class Phalcon\Forms\Element\Radio

extends abstract class [Phalcon\Forms\Element](#)

implements [Phalcon\Forms\ElementInterface](#)

Component INPUT[type=radio] for forms

Methods

`public string render ([unknown $attributes])`

Renders the element widget returning html

`public __construct (unknown $name, [unknown $attributes])` inherited from Phalcon\Forms\Element

Phalcon\Forms\Element constructor

`public Phalcon\Forms\ElementInterface setForm (unknown $form)` inherited from Phalcon\Forms\Element

Sets the parent form to the element

`public Phalcon\Forms\ElementInterface getForm ()` inherited from Phalcon\Forms\Element

Returns the parent form to the element

`public Phalcon\Forms\ElementInterface setName (unknown $name)` inherited from Phalcon\Forms\Element

Sets the element name

`public string getName ()` inherited from Phalcon\Forms\Element

Returns the element name

`public Phalcon\Forms\ElementInterface setFilters (unknown $filters)` inherited from Phalcon\Forms\Element

Sets the element filters

`public Phalcon\Forms\ElementInterface addFilter (unknown $filter)` inherited from Phalcon\Forms\Element

Adds a filter to current list of filters

`public mixed getFilters ()` inherited from Phalcon\Forms\Element

Returns the element filters

`public Phalcon\Forms\ElementInterface addValidators (unknown $validators, [unknown $merge])` inherited from Phalcon\Forms\Element

Adds a group of validators

`public Phalcon\Forms\ElementInterface addValidator (unknown $validator)` inherited from Phalcon\Forms\Element

Adds a validator to the element

`public Phalcon\Validation\ValidatorInterface [] getValidators ()` inherited from Phalcon\Forms\Element

Returns the validators registered for the element

`public array prepareAttributes ([unknown $attributes], [unknown $useChecked])` inherited from Phalcon\Forms\Element

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

`public Phalcon\Forms\ElementInterface setAttribute (unknown $attribute, unknown $value)` inherited from Phalcon\Forms\Element

Sets a default attribute for the element

`public mixed getAttribute (unknown $attribute, [unknown $defaultValue])` inherited from Phalcon\Forms\Element

Returns the value of an attribute if present

`public Phalcon\Forms\ElementInterface setAttributes (unknown $attributes)` inherited from Phalcon\Forms\Element

Sets default attributes for the element

`public array getAttributes ()` inherited from Phalcon\Forms\Element

Returns the default attributes for the element

public [Phalcon\Forms\ElementInterface](#) **setUserOption** (*unknown* \$option, *unknown* \$value) inherited from Phalcon\Forms\Element

Sets an option for the element

public *mixed* **getUserOption** (*unknown* \$option, [*unknown* \$defaultValue]) inherited from Phalcon\Forms\Element

Returns the value of an option if present

public [Phalcon\Forms\ElementInterface](#) **setUserOptions** (*unknown* \$options) inherited from Phalcon\Forms\Element

Sets options for the element

public *array* **getUserOptions** () inherited from Phalcon\Forms\Element

Returns the options for the element

public [Phalcon\Forms\ElementInterface](#) **setLabel** (*unknown* \$label) inherited from Phalcon\Forms\Element

Sets the element label

public *string* **getLabel** () inherited from Phalcon\Forms\Element

Returns the element label

public *string* **label** ([*unknown* \$attributes]) inherited from Phalcon\Forms\Element

Generate the HTML to label the element

public [Phalcon\Forms\ElementInterface](#) **setDefault** (*unknown* \$value) inherited from Phalcon\Forms\Element

Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

public *mixed* **getDefault** () inherited from Phalcon\Forms\Element

Returns the default value assigned to the element

public *mixed* **getValue** () inherited from Phalcon\Forms\Element

Returns the element value

public [Phalcon\Validation\Message\Group](#) **getMessages** () inherited from Phalcon\Forms\Element

Returns the messages that belongs to the element The element needs to be attached to a form

public *boolean* **hasMessages** () inherited from Phalcon\Forms\Element

Checks whether there are messages attached to the element

public [Phalcon\Forms\ElementInterface](#) **setMessages** (*unknown* \$group) inherited from Phalcon\Forms\Element

Sets the validation messages related to the element

public [Phalcon\Forms\ElementInterface](#) **appendMessage** (*unknown* \$message) inherited from Phalcon\Forms\Element

Appends a message to the internal message list

public [Phalcon\Forms\Element](#) **clear** () inherited from Phalcon\Forms\Element

Clears every element in the form to its default value

public *string* **__toString** () inherited from Phalcon\Forms\Element

Magic method __toString renders the widget without attributes

2.58.99 Class Phalcon\Forms\Element>Select

extends abstract class [Phalcon\Forms\Element](#)

implements [Phalcon\Forms\ElementInterface](#)

Component SELECT (choice) for forms

Methods

public __construct (*unknown* \$name, [*unknown* \$options], [*unknown* \$attributes])

Phalcon\Forms\Element constructor

public Phalcon\Forms\Element setOptions (*unknown* \$options)

Set the choice's options

public array|object getOptions ()

Returns the choices' options

public this addOption (*unknown* \$option)

Adds an option to the current options

public string render ([*unknown* \$attributes])

Renders the element widget returning html

public Phalcon\Forms\ElementInterface setForm (*unknown* \$form) inherited from Phalcon\Forms\Element

Sets the parent form to the element

public Phalcon\Forms\ElementInterface getForm () inherited from Phalcon\Forms\Element

Returns the parent form to the element

public Phalcon\Forms\ElementInterface setName (*unknown* \$name) inherited from Phalcon\Forms\Element

Sets the element name

public string getName () inherited from Phalcon\Forms\Element

Returns the element name

public Phalcon\Forms\ElementInterface setFilters (*unknown* \$filters) inherited from Phalcon\Forms\Element

Sets the element filters

public Phalcon\Forms\ElementInterface addFilter (*unknown* \$filter) inherited from Phalcon\Forms\Element

Adds a filter to current list of filters

public mixed getFilters () inherited from Phalcon\Forms\Element

Returns the element filters

public Phalcon\Forms\ElementInterface addValidators (*unknown* \$validators, [*unknown* \$merge]) inherited from Phalcon\Forms\Element

Adds a group of validators

public Phalcon\Forms\ElementInterface addValidator (*unknown* \$validator) inherited from Phalcon\Forms\Element

Adds a validator to the element

public Phalcon\Validation\ValidatorInterface [] getValidators () inherited from Phalcon\Forms\Element

Returns the validators registered for the element

public *array* **prepareAttributes** ([*unknown* \$attributes], [*unknown* \$useChecked]) inherited from Phalcon\Forms\Element

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

public *Phalcon\Forms\ElementInterface* **setAttribute** (*unknown* \$attribute, *unknown* \$value) inherited from Phalcon\Forms\Element

Sets a default attribute for the element

public *mixed* **getAttribute** (*unknown* \$attribute, [*unknown* \$defaultValue]) inherited from Phalcon\Forms\Element

Returns the value of an attribute if present

public *Phalcon\Forms\ElementInterface* **setAttributes** (*unknown* \$attributes) inherited from Phalcon\Forms\Element

Sets default attributes for the element

public *array* **getAttributes** () inherited from Phalcon\Forms\Element

Returns the default attributes for the element

public *Phalcon\Forms\ElementInterface* **setUserOption** (*unknown* \$option, *unknown* \$value) inherited from Phalcon\Forms\Element

Sets an option for the element

public *mixed* **getUserOption** (*unknown* \$option, [*unknown* \$defaultValue]) inherited from Phalcon\Forms\Element

Returns the value of an option if present

public *Phalcon\Forms\ElementInterface* **setUserOptions** (*unknown* \$options) inherited from Phalcon\Forms\Element

Sets options for the element

public *array* **getUserOptions** () inherited from Phalcon\Forms\Element

Returns the options for the element

public *Phalcon\Forms\ElementInterface* **setLabel** (*unknown* \$label) inherited from Phalcon\Forms\Element

Sets the element label

public *string* **getLabel** () inherited from Phalcon\Forms\Element

Returns the element label

public *string* **label** ([*unknown* \$attributes]) inherited from Phalcon\Forms\Element

Generate the HTML to label the element

public *Phalcon\Forms\ElementInterface* **setDefault** (*unknown* \$value) inherited from Phalcon\Forms\Element

Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

public *mixed* **getDefault** () inherited from Phalcon\Forms\Element

Returns the default value assigned to the element

public *mixed* **getValue** () inherited from Phalcon\Forms\Element

Returns the element value

public *Phalcon\Validation\Message\Group* **getMessages** () inherited from Phalcon\Forms\Element

Returns the messages that belongs to the element The element needs to be attached to a form

public *boolean* **hasMessages** () inherited from Phalcon\Forms\Element

Checks whether there are messages attached to the element

public [Phalcon\Forms\ElementInterface](#) **setMessages** (*unknown* \$group) inherited from [Phalcon\Forms\Element](#)

Sets the validation messages related to the element

public [Phalcon\Forms\ElementInterface](#) **appendMessage** (*unknown* \$message) inherited from [Phalcon\Forms\Element](#)

Appends a message to the internal message list

public [Phalcon\Forms\Element](#) **clear** () inherited from [Phalcon\Forms\Element](#)

Clears every element in the form to its default value

public *string* **__toString** () inherited from [Phalcon\Forms\Element](#)

Magic method **__toString** renders the widget without attributes

2.58.100 Class Phalcon\Forms\Element\Submit

extends abstract class [Phalcon\Forms\Element](#)

implements [Phalcon\Forms\ElementInterface](#)

Component INPUT[type=submit] for forms

Methods

public *string* **render** ([*unknown* \$attributes])

Renders the element widget

public **__construct** (*unknown* \$name, [*unknown* \$attributes]) inherited from [Phalcon\Forms\Element](#)

Phalcon\Forms\Element constructor

public [Phalcon\Forms\ElementInterface](#) **setForm** (*unknown* \$form) inherited from [Phalcon\Forms\Element](#)

Sets the parent form to the element

public [Phalcon\Forms\ElementInterface](#) **getForm** () inherited from [Phalcon\Forms\Element](#)

Returns the parent form to the element

public [Phalcon\Forms\ElementInterface](#) **setName** (*unknown* \$name) inherited from [Phalcon\Forms\Element](#)

Sets the element name

public *string* **getName** () inherited from [Phalcon\Forms\Element](#)

Returns the element name

public [Phalcon\Forms\ElementInterface](#) **setFilters** (*unknown* \$filters) inherited from [Phalcon\Forms\Element](#)

Sets the element filters

public [Phalcon\Forms\ElementInterface](#) **addFilter** (*unknown* \$filter) inherited from [Phalcon\Forms\Element](#)

Adds a filter to current list of filters

public *mixed* **getFilters** () inherited from [Phalcon\Forms\Element](#)

Returns the element filters

public [Phalcon\Forms\ElementInterface](#) **addValidators** (*unknown* \$validators, [*unknown* \$merge]) inherited from [Phalcon\Forms\Element](#)

Adds a group of validators

public [Phalcon\Forms\ElementInterface](#) **addValidator** (*unknown* \$validator) inherited from [Phalcon\Forms\Element](#)

Adds a validator to the element

public [Phalcon\Validation\ValidatorInterface](#) [] **getValidators** () inherited from [Phalcon\Forms\Element](#)

Returns the validators registered for the element

public *array* **prepareAttributes** ([*unknown* \$attributes], [*unknown* \$useChecked]) inherited from [Phalcon\Forms\Element](#)

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

public [Phalcon\Forms\ElementInterface](#) **setAttribute** (*unknown* \$attribute, *unknown* \$value) inherited from [Phalcon\Forms\Element](#)

Sets a default attribute for the element

public *mixed* **getAttribute** (*unknown* \$attribute, [*unknown* \$defaultValue]) inherited from [Phalcon\Forms\Element](#)

Returns the value of an attribute if present

public [Phalcon\Forms\ElementInterface](#) **setAttributes** (*unknown* \$attributes) inherited from [Phalcon\Forms\Element](#)

Sets default attributes for the element

public *array* **getAttributes** () inherited from [Phalcon\Forms\Element](#)

Returns the default attributes for the element

public [Phalcon\Forms\ElementInterface](#) **setUserOption** (*unknown* \$option, *unknown* \$value) inherited from [Phalcon\Forms\Element](#)

Sets an option for the element

public *mixed* **getUserOption** (*unknown* \$option, [*unknown* \$defaultValue]) inherited from [Phalcon\Forms\Element](#)

Returns the value of an option if present

public [Phalcon\Forms\ElementInterface](#) **setUserOptions** (*unknown* \$options) inherited from [Phalcon\Forms\Element](#)

Sets options for the element

public *array* **getUserOptions** () inherited from [Phalcon\Forms\Element](#)

Returns the options for the element

public [Phalcon\Forms\ElementInterface](#) **setLabel** (*unknown* \$label) inherited from [Phalcon\Forms\Element](#)

Sets the element label

public *string* **getLabel** () inherited from [Phalcon\Forms\Element](#)

Returns the element label

public *string* **label** ([*unknown* \$attributes]) inherited from [Phalcon\Forms\Element](#)

Generate the HTML to label the element

public [Phalcon\Forms\ElementInterface](#) **setDefault** (*unknown* \$value) inherited from [Phalcon\Forms\Element](#)

Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

public *mixed* **getDefault** () inherited from [Phalcon\Forms\Element](#)

Returns the default value assigned to the element

`public mixed getValue ()` inherited from `Phalcon\Forms\Element`

Returns the element value

`public Phalcon\Validation\Message\Group getMessages ()` inherited from `Phalcon\Forms\Element`

Returns the messages that belongs to the element The element needs to be attached to a form

`public boolean hasMessages ()` inherited from `Phalcon\Forms\Element`

Checks whether there are messages attached to the element

`public Phalcon\Forms\ElementInterface setMessages (unknown $group)` inherited from `Phalcon\Forms\Element`

Sets the validation messages related to the element

`public Phalcon\Forms\ElementInterface appendMessage (unknown $message)` inherited from `Phalcon\Forms\Element`

Appends a message to the internal message list

`public Phalcon\Forms\Element clear ()` inherited from `Phalcon\Forms\Element`

Clears every element in the form to its default value

`public string __toString ()` inherited from `Phalcon\Forms\Element`

Magic method `__toString` renders the widget without attributes

2.58.101 Class `Phalcon\Forms\Element\Text`

extends abstract class `Phalcon\Forms\Element`

implements `Phalcon\Forms\ElementInterface`

Component INPUT[type=text] for forms

Methods

`public string render ([unknown $attributes])`

Renders the element widget

`public __construct (unknown $name, [unknown $attributes])` inherited from `Phalcon\Forms\Element`

Phalcon\Forms\Element constructor

`public Phalcon\Forms\ElementInterface setForm (unknown $form)` inherited from `Phalcon\Forms\Element`

Sets the parent form to the element

`public Phalcon\Forms\ElementInterface getForm ()` inherited from `Phalcon\Forms\Element`

Returns the parent form to the element

`public Phalcon\Forms\ElementInterface setName (unknown $name)` inherited from `Phalcon\Forms\Element`

Sets the element name

`public string getName ()` inherited from `Phalcon\Forms\Element`

Returns the element name

`public Phalcon\Forms\ElementInterface setFilters (unknown $filters)` inherited from `Phalcon\Forms\Element`

Sets the element filters

public `Phalcon\Forms\ElementInterface` **addFilter** (*unknown* \$filter) inherited from `Phalcon\Forms\Element`

Adds a filter to current list of filters

public *mixed* **getFilters** () inherited from `Phalcon\Forms\Element`

Returns the element filters

public `Phalcon\Forms\ElementInterface` **addValidators** (*unknown* \$validators, [*unknown* \$merge]) inherited from `Phalcon\Forms\Element`

Adds a group of validators

public `Phalcon\Forms\ElementInterface` **addValidator** (*unknown* \$validator) inherited from `Phalcon\Forms\Element`

Adds a validator to the element

public `Phalcon\Validation\ValidatorInterface` [] **getValidators** () inherited from `Phalcon\Forms\Element`

Returns the validators registered for the element

public *array* **prepareAttributes** ([*unknown* \$attributes], [*unknown* \$useChecked]) inherited from `Phalcon\Forms\Element`

Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

public `Phalcon\Forms\ElementInterface` **setAttribute** (*unknown* \$attribute, *unknown* \$value) inherited from `Phalcon\Forms\Element`

Sets a default attribute for the element

public *mixed* **getAttribute** (*unknown* \$attribute, [*unknown* \$defaultValue]) inherited from `Phalcon\Forms\Element`

Returns the value of an attribute if present

public `Phalcon\Forms\ElementInterface` **setAttributes** (*unknown* \$attributes) inherited from `Phalcon\Forms\Element`

Sets default attributes for the element

public *array* **getAttributes** () inherited from `Phalcon\Forms\Element`

Returns the default attributes for the element

public `Phalcon\Forms\ElementInterface` **setUserOption** (*unknown* \$option, *unknown* \$value) inherited from `Phalcon\Forms\Element`

Sets an option for the element

public *mixed* **getUserOption** (*unknown* \$option, [*unknown* \$defaultValue]) inherited from `Phalcon\Forms\Element`

Returns the value of an option if present

public `Phalcon\Forms\ElementInterface` **setUserOptions** (*unknown* \$options) inherited from `Phalcon\Forms\Element`

Sets options for the element

public *array* **getUserOptions** () inherited from `Phalcon\Forms\Element`

Returns the options for the element

public `Phalcon\Forms\ElementInterface` **setLabel** (*unknown* \$label) inherited from `Phalcon\Forms\Element`

Sets the element label

public *string* **getLabel** () inherited from `Phalcon\Forms\Element`

Returns the element label

public *string* **label** ([*unknown* \$attributes]) inherited from Phalcon\Forms\Element

Generate the HTML to label the element

public Phalcon\Forms\ElementInterface **setDefault** (*unknown* \$value) inherited from Phalcon\Forms\Element

Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

public *mixed* **getDefault** () inherited from Phalcon\Forms\Element

Returns the default value assigned to the element

public *mixed* **getValue** () inherited from Phalcon\Forms\Element

Returns the element value

public Phalcon\Validation\Message\Group **getMessages** () inherited from Phalcon\Forms\Element

Returns the messages that belongs to the element The element needs to be attached to a form

public *boolean* **hasMessages** () inherited from Phalcon\Forms\Element

Checks whether there are messages attached to the element

public Phalcon\Forms\ElementInterface **setMessages** (*unknown* \$group) inherited from Phalcon\Forms\Element

Sets the validation messages related to the element

public Phalcon\Forms\ElementInterface **appendMessage** (*unknown* \$message) inherited from Phalcon\Forms\Element

Appends a message to the internal message list

public Phalcon\Forms\Element **clear** () inherited from Phalcon\Forms\Element

Clears every element in the form to its default value

public *string* **_toString** () inherited from Phalcon\Forms\Element

Magic method __toString renders the widget without attributes

2.58.102 Class Phalcon\Forms\Element\TextArea

extends abstract class Phalcon\Forms\Element

implements Phalcon\Forms\ElementInterface

Component TEXTAREA for forms

Methods

public *string* **render** ([*unknown* \$attributes])

Renders the element widget

public **__construct** (*unknown* \$name, [*unknown* \$attributes]) inherited from Phalcon\Forms\Element

Phalcon\Forms\Element constructor

public Phalcon\Forms\ElementInterface **setForm** (*unknown* \$form) inherited from Phalcon\Forms\Element

Sets the parent form to the element

public Phalcon\Forms\ElementInterface **getForm** () inherited from Phalcon\Forms\Element

Returns the parent form to the element

public `Phalcon\Forms\ElementInterface` **setName** (*unknown \$name*) inherited from `Phalcon\Forms\Element`
Sets the element name

public `string` **getName** () inherited from `Phalcon\Forms\Element`
Returns the element name

public `Phalcon\Forms\ElementInterface` **setFilters** (*unknown \$filters*) inherited from `Phalcon\Forms\Element`
Sets the element filters

public `Phalcon\Forms\ElementInterface` **addFilter** (*unknown \$filter*) inherited from `Phalcon\Forms\Element`
Adds a filter to current list of filters

public `mixed` **getFilters** () inherited from `Phalcon\Forms\Element`
Returns the element filters

public `Phalcon\Forms\ElementInterface` **addValidators** (*unknown \$validators*, [*unknown \$merge*]) inherited from `Phalcon\Forms\Element`
Adds a group of validators

public `Phalcon\Forms\ElementInterface` **addValidator** (*unknown \$validator*) inherited from `Phalcon\Forms\Element`
Adds a validator to the element

public `Phalcon\Validation\ValidatorInterface []` **getValidators** () inherited from `Phalcon\Forms\Element`
Returns the validators registered for the element

public `array` **prepareAttributes** ([*unknown \$attributes*], [*unknown \$useChecked*]) inherited from `Phalcon\Forms\Element`
Returns an array of prepared attributes for Phalcon\Tag helpers according to the element parameters

public `Phalcon\Forms\ElementInterface` **setAttribute** (*unknown \$attribute*, *unknown \$value*) inherited from `Phalcon\Forms\Element`
Sets a default attribute for the element

public `mixed` **getAttribute** (*unknown \$attribute*, [*unknown \$defaultValue*]) inherited from `Phalcon\Forms\Element`
Returns the value of an attribute if present

public `Phalcon\Forms\ElementInterface` **setAttributes** (*unknown \$attributes*) inherited from `Phalcon\Forms\Element`
Sets default attributes for the element

public `array` **getAttributes** () inherited from `Phalcon\Forms\Element`
Returns the default attributes for the element

public `Phalcon\Forms\ElementInterface` **setUserOption** (*unknown \$option*, *unknown \$value*) inherited from `Phalcon\Forms\Element`
Sets an option for the element

public `mixed` **getUserOption** (*unknown \$option*, [*unknown \$defaultValue*]) inherited from `Phalcon\Forms\Element`
Returns the value of an option if present

public `Phalcon\Forms\ElementInterface` **setUserOptions** (*unknown \$options*) inherited from `Phalcon\Forms\Element`
Sets options for the element

public `array` **getUserOptions** () inherited from `Phalcon\Forms\Element`

Returns the options for the element

public [Phalcon\Forms\ElementInterface](#) **setLabel** (*unknown* \$label) inherited from [Phalcon\Forms\Element](#)

Sets the element label

public *string* **getLabel** () inherited from [Phalcon\Forms\Element](#)

Returns the element label

public *string* **label** ([*unknown* \$attributes]) inherited from [Phalcon\Forms\Element](#)

Generate the HTML to label the element

public [Phalcon\Forms\ElementInterface](#) **setDefault** (*unknown* \$value) inherited from [Phalcon\Forms\Element](#)

Sets a default value in case the form does not use an entity or there is no value available for the element in _POST

public *mixed* **getDefault** () inherited from [Phalcon\Forms\Element](#)

Returns the default value assigned to the element

public *mixed* **getValue** () inherited from [Phalcon\Forms\Element](#)

Returns the element value

public [Phalcon\Validation\Message\Group](#) **getMessages** () inherited from [Phalcon\Forms\Element](#)

Returns the messages that belongs to the element The element needs to be attached to a form

public *boolean* **hasMessages** () inherited from [Phalcon\Forms\Element](#)

Checks whether there are messages attached to the element

public [Phalcon\Forms\ElementInterface](#) **setMessages** (*unknown* \$group) inherited from [Phalcon\Forms\Element](#)

Sets the validation messages related to the element

public [Phalcon\Forms\ElementInterface](#) **appendMessage** (*unknown* \$message) inherited from [Phalcon\Forms\Element](#)

Appends a message to the internal message list

public [Phalcon\Forms\Element](#) **clear** () inherited from [Phalcon\Forms\Element](#)

Clears every element in the form to its default value

public *string* **__toString** () inherited from [Phalcon\Forms\Element](#)

Magic method __toString renders the widget without attributes

2.58.103 Class Phalcon\Forms\Exception

extends class [Phalcon\Exception](#)

Methods

final private *Exception* **__clone** () inherited from [Exception](#)

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from [Exception](#)

Exception constructor

final public *string* **getMessage** () inherited from [Exception](#)

Gets the Exception message
final public *int* **getCode** () inherited from Exception
Gets the Exception code
final public *string* **getFile** () inherited from Exception
Gets the file in which the exception occurred
final public *int* **getLine** () inherited from Exception
Gets the line in which the exception occurred
final public *array* **getTrace** () inherited from Exception
Gets the stack trace
final public *Exception* **getPrevious** () inherited from Exception
Returns previous Exception
final public *Exception* **getTraceAsString** () inherited from Exception
Gets the stack trace as a string
public *string* **__toString** () inherited from Exception
String representation of the exception

2.58.104 Class Phalcon\Forms\Form

extends abstract class Phalcon\Di\Injectable
implements Phalcon\Events\EventsAwareInterface, Phalcon\Di\InjectionAwareInterface, Countable, Iterator, Traversable
This component allows to build forms using an object-oriented interface

Methods

public **setValidation** (*unknown* \$validation)
...
public **getValidation** ()
...
public **__construct** ([*unknown* \$entity], [*unknown* \$userOptions])
Phalcon\Forms\Form constructor
public Phalcon\Forms\Form **setAction** (*unknown* \$action)
Sets the form's action
public *string* **getAction** ()
Returns the form's action
public Phalcon\Forms\Form **setUserOption** (*unknown* \$option, *unknown* \$value)
Sets an option for the form
public *mixed* **getUserOption** (*unknown* \$option, [*unknown* \$defaultValue])

Returns the value of an option if present

`public Phalcon\Forms\Form setUserOptions (unknown $options)`

Sets options for the element

`public array getUserOptions ()`

Returns the options for the element

`public Phalcon\Forms\Form setEntity (unknown $entity)`

Sets the entity related to the model

`public object getEntity ()`

Returns the entity related to the model

`public Phalcon\Forms\ElementInterface [] getElements ()`

Returns the form elements added to the form

`public Phalcon\Forms\Form bind (unknown $data, unknown $entity, [unknown $whitelist])`

Binds data to the entity

`public boolean isValid ([unknown $data], [unknown $entity])`

Validates the form

`public array getMessages ([unknown $byItemName])`

Returns the messages generated in the validation

`public Phalcon\Validation\Message\Group getMessagesFor (unknown $name)`

Returns the messages generated for a specific element

`public boolean hasMessagesFor (unknown $name)`

Check if messages were generated for a specific element

`public Phalcon\Forms\Form add (unknown $element, [string $position], [unknown $type])`

Adds an element to the form

`public string render (unknown $name, [unknown $attributes])`

Renders a specific item in the form

`public Phalcon\Forms\ElementInterface get (unknown $name)`

Returns an element added to the form by its name

`public string label (unknown $name, [unknown $attributes])`

Generate the label of a element added to the form including HTML

`public string getLabel (unknown $name)`

Returns a label for an element

`public mixed getValue (unknown $name)`

Gets a value from the internal related entity or from the default value

`public boolean has (unknown $name)`

Check if the form contains an element

`public boolean remove (unknown $name)`

Removes an element from the form

public `Phalcon\Forms\Form` **clear** ([*unknown \$fields*])

Clears every element in the form to its default value

public *int* **count** ()

Returns the number of elements in the form

public **rewind** ()

Rewinds the internal iterator

public `Phalcon\Forms\ElementInterface` **current** ()

Returns the current element in the iterator

public *int* **key** ()

Returns the current position/key in the iterator

public **next** ()

Moves the internal iteration pointer to the next position

public *boolean* **valid** ()

Check if the current element in the iterator is valid

public **setDI** (*unknown \$dependencyInjector*) inherited from `Phalcon\Di\Injectable`

Sets the dependency injector

public `Phalcon\DiInterface` **getDI** () inherited from `Phalcon\Di\Injectable`

Returns the internal dependency injector

public **setEventsManager** (*unknown \$eventsManager*) inherited from `Phalcon\Di\Injectable`

Sets the event manager

public `Phalcon\Events\ManagerInterface` **getEventsManager** () inherited from `Phalcon\Di\Injectable`

Returns the internal event manager

public **__get** (*unknown \$propertyName*) inherited from `Phalcon\Di\Injectable`

Magic method `__get`

2.58.105 Class `Phalcon\Forms\Manager`

Methods

public `Phalcon\Forms\Form` **create** ([*unknown \$name*], [*unknown \$entity*])

Creates a form registering it in the forms manager

public `Phalcon\Forms\Form` **get** (*unknown \$name*)

Returns a form by its name

public *boolean* **has** (*unknown \$name*)

Checks if a form is registered in the forms manager

public `Phalcon\Forms\FormManager` **set** (*unknown \$name*, *unknown \$form*)

Registers a form in the Forms Manager

2.58.106 Class Phalcon\Http\Cookie

implements Phalcon\Di\InjectionAwareInterface

Provide OO wrappers to manage a HTTP cookie

Methods

public **__construct** (*unknown* \$name, [*unknown* \$value], [*unknown* \$expire], [*unknown* \$path], [*unknown* \$secure], [*unknown* \$domain], [*unknown* \$httpOnly])

Phalcon\Http\Cookie constructor

public **setDI** (*unknown* \$dependencyInjector)

Sets the dependency injector

public Phalcon\DiInterface **getDI** ()

Returns the internal dependency injector

public Phalcon\Http\Cookie **setValue** (*unknown* \$value)

Sets the cookie's value

public *mixed* **getValue** ([*unknown* \$filters], [*unknown* \$defaultValue])

Returns the cookie's value

public Phalcon\Http\Cookie **send** ()

Sends the cookie to the HTTP client Stores the cookie definition in session

public Phalcon\Http\Cookie **restore** ()

Reads the cookie-related info from the SESSION to restore the cookie as it was set This method is automatically called internally so normally you don't need to call it

public **delete** ()

Deletes the cookie by setting an expire time in the past

public Phalcon\Http\Cookie **useEncryption** (*unknown* \$useEncryption)

Sets if the cookie must be encrypted/decrypted automatically

public boolean **isUsingEncryption** ()

Check if the cookie is using implicit encryption

public Phalcon\Http\Cookie **setExpiration** (*unknown* \$expire)

Sets the cookie's expiration time

public string **getExpiration** ()

Returns the current expiration time

public Phalcon\Http\Cookie **setPath** (*unknown* \$path)

Sets the cookie's expiration time

public string **getName** ()

Returns the current cookie's name

`public string getPath ()`

Returns the current cookie's path

`public Phalcon\Http\Cookie setDomain (unknown $domain)`

Sets the domain that the cookie is available to

`public string getDomain ()`

Returns the domain that the cookie is available to

`public Phalcon\Http\Cookie setSecure (unknown $secure)`

Sets if the cookie must only be sent when the connection is secure (HTTPS)

`public boolean getSecure ()`

Returns whether the cookie must only be sent when the connection is secure (HTTPS)

`public Phalcon\Http\Cookie setHttpOnly (unknown $httpOnly)`

Sets if the cookie is accessible only through the HTTP protocol

`public boolean getHttpOnly ()`

Returns if the cookie is accessible only through the HTTP protocol

`public string __toString ()`

Magic __toString method converts the cookie's value to string

2.58.107 Class Phalcon\Http\Cookie\Exception

extends class Phalcon\Exception

Methods

`final private Exception __clone ()` inherited from Exception

Clone the exception

`public __construct ([string $message], [int $code], [Exception $previous])` inherited from Exception

Exception constructor

`final public string getMessage ()` inherited from Exception

Gets the Exception message

`final public int getCode ()` inherited from Exception

Gets the Exception code

`final public string getFile ()` inherited from Exception

Gets the file in which the exception occurred

`final public int getLine ()` inherited from Exception

Gets the line in which the exception occurred

`final public array getTrace ()` inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from *Exception*

Returns previous *Exception*

final public *Exception* **getTraceAsString** () inherited from *Exception*

Gets the stack trace as a string

public *string* **__toString** () inherited from *Exception*

String representation of the exception

2.58.108 Class Phalcon\Http\Request

implements `Phalcon\Http\RequestInterface, Phalcon\Di\InjectionAwareInterface`

Encapsulates request information for easy and secure access from application controllers. The request object is a simple value object that is passed between the dispatcher and controller classes. It packages the HTTP request environment.

```
<?php

$request = new \Phalcon\Http\Request();
if ($request->isPost() == true) {
    if ($request->isAjax() == true) {
        echo 'Request was made using POST and AJAX';
    }
}
```

Methods

public **setDI** (*unknown* \$dependencyInjector)

Sets the dependency injector

public `Phalcon\DiInterface` **getDI** ()

Returns the internal dependency injector

public *mixed* **get** ([*unknown* \$name], [*unknown* \$filters], [*unknown* \$defaultValue], [*unknown* \$notAllowEmpty], [*unknown* \$noRecursive])

Gets a variable from the `$_REQUEST` superglobal applying filters if needed. If no parameters are given the `$_REQUEST` superglobal is returned

```
<?php

//Returns value from $_REQUEST["user_email"] without sanitizing
$userEmail = $request->get("user_email");

//Returns value from $_REQUEST["user_email"] with sanitizing
$userEmail = $request->get("user_email", "email");
```

public *mixed* **getPost** ([*unknown* \$name], [*unknown* \$filters], [*unknown* \$defaultValue], [*unknown* \$notAllowEmpty], [*unknown* \$noRecursive])

Gets a variable from the `$_POST` superglobal applying filters if needed If no parameters are given the `$_POST` superglobal is returned

```
<?php

//Returns value from $_POST["user_email"] without sanitizing
$userEmail = $request->getPost("user_email");

//Returns value from $_POST["user_email"] with sanitizing
$userEmail = $request->getPost("user_email", "email");
```

public *mixed* **getPut** ([*unknown* \$name], [*unknown* \$filters], [*unknown* \$defaultValue], [*unknown* \$notAllowEmpty], [*unknown* \$noRecursive])

Gets a variable from put request

```
<?php

//Returns value from $_PUT["user_email"] without sanitizing
$userEmail = $request->getPut("user_email");

//Returns value from $_PUT["user_email"] with sanitizing
$userEmail = $request->getPut("user_email", "email");
```

public *mixed* **getQuery** ([*unknown* \$name], [*unknown* \$filters], [*unknown* \$defaultValue], [*unknown* \$notAllowEmpty], [*unknown* \$noRecursive])

Gets variable from \$_GET superglobal applying filters if needed If no parameters are given the \$_GET superglobal is returned

```
<?php

//Returns value from $_GET["id"] without sanitizing
$id = $request->getQuery("id");

//Returns value from $_GET["id"] with sanitizing
$id = $request->getQuery("id", "int");

//Returns value from $_GET["id"] with a default value
$id = $request->getQuery("id", null, 150);
```

public *mixed* **getServer** (*unknown* \$name)

Gets variable from \$_SERVER superglobal

public *boolean* **has** (*unknown* \$name)

Checks whether \$_REQUEST superglobal has certain index

public *boolean* **hasPost** (*string* \$name)

Checks whether \$_POST superglobal has certain index

public *boolean* **hasQuery** (*unknown* \$name)

Checks whether \$_GET superglobal has certain index

final public *boolean* **hasServer** (*unknown* \$name)

Checks whether \$_SERVER superglobal has certain index

final public *string* **getHeader** (*unknown* \$header)

Gets HTTP header from request data

public *string* **getScheme** ()

Gets HTTP schema (http/https)

public boolean isAjax ()

Checks whether request has been made using ajax

public boolean isSoapRequested ()

Checks whether request has been made using SOAP

public boolean isSecureRequest ()

Checks whether request has been made using any secure layer

public string getRawBody ()

Gets HTTP raw request body

public string getJsonRawBody ([*unknown* \$associative])

Gets decoded JSON HTTP raw request body

public string getServerAddress ()

Gets active server address IP

public string getServerName ()

Gets active server name

public string getHttpHost ()

Gets information about schema, host and port used by the request

final public string getURI ()

Gets HTTP URI which request has been made

public string|boolean getClientAddress ([*unknown* \$trustForwardedHeader])

Gets most possible client IPv4 Address. This method search in `_SERVER['REMOTE_ADDR']` and optionally in `_SERVER['HTTP_X_FORWARDED_FOR']`

final public string getMethod ()

Gets HTTP method which request has been made

public string getUserAgent ()

Gets HTTP user agent used to made the request

public boolean isMethod (*unknown* \$methods)

Check if HTTP method match any of the passed methods

public boolean isPost ()

Checks whether HTTP method is POST. if `_SERVER["REQUEST_METHOD"]`==="POST"

public boolean isGet ()

Checks whether HTTP method is GET. if `_SERVER["REQUEST_METHOD"]`==="GET"

public boolean isPut ()

Checks whether HTTP method is PUT. if `_SERVER["REQUEST_METHOD"]`==="PUT"

public boolean isPatch ()

Checks whether HTTP method is PATCH. if `_SERVER["REQUEST_METHOD"]`==="PATCH"

public *boolean* **isHead** ()

Checks whether HTTP method is HEAD. if `_SERVER["REQUEST_METHOD"]==="HEAD"`

public *boolean* **isDelete** ()

Checks whether HTTP method is DELETE. if `_SERVER["REQUEST_METHOD"]==="DELETE"`

public *boolean* **isOptions** ()

Checks whether HTTP method is OPTIONS. if `_SERVER["REQUEST_METHOD"]==="OPTIONS"`

public *boolean* **hasFiles** ([*unknown* \$onlySuccessful])

Checks whether request include attached files

private **hasFileHelper** (*unknown* \$data, *unknown* \$onlySuccessful)

...

public **Phalcon\Http\Request\File** [] **getUploadedFiles** ([*unknown* \$notErrored])

Gets attached files as Phalcon\Http\Request\File instances

protected *array* **smoothFiles** (*unknown* \$names, *unknown* \$types, *unknown* \$tmp_names, *unknown* \$sizes, *unknown* \$errors, *unknown* \$prefix)

smooth out `$_FILES` to have plain array with all files uploaded

public *array* **getHeaders** ()

Returns the available headers in the request

public *string* **getHTTPReferer** ()

Gets web page that refers active request. ie: <http://www.google.com>

protected *array* **_getQualityHeader** (*unknown* \$serverIndex, *unknown* \$name)

Process a request header and return an array of values with their qualities

protected *string* **_getBestQuality** (*unknown* \$qualityParts, *unknown* \$name)

Process a request header and return the one with best quality

public *mixed* **getContentType** ()

Gets content type which request has been made

public *array* **getAcceptableContent** ()

Gets array with mime/types and their quality accepted by the browser/client from `_SERVER["HTTP_ACCEPT"]`

public *string* **getBestAccept** ()

Gets best mime/type accepted by the browser/client from `_SERVER["HTTP_ACCEPT"]`

public *array* **getClientCharsets** ()

Gets charsets array and their quality accepted by the browser/client from `_SERVER["HTTP_ACCEPT_CHARSET"]`

public *string* **getBestCharset** ()

Gets best charset accepted by the browser/client from `_SERVER["HTTP_ACCEPT_CHARSET"]`

public *array* **getLanguages** ()

Gets languages array and their quality accepted by the browser/client from `_SERVER["HTTP_ACCEPT_LANGUAGE"]`

public *string* **getBestLanguage** ()

Gets best language accepted by the browser/client from `_SERVER["HTTP_ACCEPT_LANGUAGE"]`

`public array getBasicAuth ()`

Gets auth info accepted by the browser/client from `$_SERVER['PHP_AUTH_USER']`

`public array getDigestAuth ()`

Gets auth info accepted by the browser/client from `$_SERVER['PHP_AUTH_DIGEST']`

2.58.109 Class Phalcon\Http\Request\Exception

extends class Phalcon\Exception

Methods

`final private Exception __clone ()` inherited from `Exception`

Clone the exception

`public __construct ([string $message], [int $code], [Exception $previous])` inherited from `Exception`

Exception constructor

`final public string getMessage ()` inherited from `Exception`

Gets the Exception message

`final public int getCode ()` inherited from `Exception`

Gets the Exception code

`final public string getFile ()` inherited from `Exception`

Gets the file in which the exception occurred

`final public int getLine ()` inherited from `Exception`

Gets the line in which the exception occurred

`final public array getTrace ()` inherited from `Exception`

Gets the stack trace

`final public Exception getPrevious ()` inherited from `Exception`

Returns previous Exception

`final public Exception getTraceAsString ()` inherited from `Exception`

Gets the stack trace as a string

`public string __toString ()` inherited from `Exception`

String representation of the exception

2.58.110 Class Phalcon\Http\Request\File

implements Phalcon\Http\Request\FileInterface

Provides OO wrappers to the `$_FILES` superglobal

```
<?php

class PostsController extends \Phalcon\Mvc\Controller
{

    public function uploadAction()
    {
        //Check if the user has uploaded files
        if ($this->request->hasFiles() == true) {
            //Print the real file names and their sizes
            foreach ($this->request->getUploadedFiles() as $file){
                echo $file->getName(), " ", $file->getSize(), "\n";
            }
        }
    }
}
```

Methods

public **getError** ()

...

public **getKey** ()

...

public **getExtension** ()

...

public **__construct** (*unknown* \$file, [*unknown* \$key])

Phalcon\Http\Request\File constructor

public **int getSize** ()

Returns the file size of the uploaded file

public **string getName** ()

Returns the real name of the uploaded file

public **string getTempName** ()

Returns the temporal name of the uploaded file

public **string getType** ()

Returns the mime type reported by the browser This mime type is not completely secure, use getRealType() instead

public **string getRealType** ()

Gets the real mime type of the upload file using finfo

public **boolean isUploadedFile** ()

Checks whether the file has been uploaded via Post.

public **boolean moveTo** (*unknown* \$destination)

Moves the temporary file to a destination within the application

2.58.111 Class Phalcon\Http\Response

implements Phalcon\Http\ResponseInterface, Phalcon\Di\InjectionAwareInterface

Part of the HTTP cycle is return responses to the clients. Phalcon\HTTP\Response is the Phalcon component responsible to achieve this task. HTTP responses are usually composed by headers and body.

```
<?php

$response = new \Phalcon\Http\Response();
$response->setStatusCode(200, "OK");
$response->setContent("<html><body>Hello</body></html>");
$response->send();
```

Methods

public __construct ([*unknown* \$content], [*unknown* \$code], [*unknown* \$status])

Phalcon\Http\Response constructor

public setDI (*unknown* \$dependencyInjector)

Sets the dependency injector

public Phalcon\DiInterface getDI ()

Returns the internal dependency injector

public Phalcon\Http\ResponseInterface setStatusCode (*unknown* \$code, [*unknown* \$message])

Sets the HTTP response code

```
<?php

$response->setStatusCode(404, "Not Found");
```

public Phalcon\Http\ResponseInterface setHeaders (*unknown* \$headers)

Sets a headers bag for the response externally

public Phalcon\Http\Response\HeadersInterface getHeaders ()

Returns headers set by the user

public Phalcon\Http\ResponseInterface setCookies (*unknown* \$cookies)

Sets a cookies bag for the response externally

public Phalcon\Http\Response\CookiesInterface getCookies ()

Returns cookies set by the user

public Phalcon\Http\ResponseInterface setHeader (*unknown* \$name, *unknown* \$value)

Overwrites a header in the response

```
<?php

$response->setHeader("Content-Type", "text/plain");
```

public Phalcon\Http\ResponseInterface setRawHeader (*unknown* \$header)

Send a raw header to the response

```
<?php  
  
$response->setRawHeader("HTTP/1.1 404 Not Found");
```

public Phalcon\Http\ResponseInterface resetHeaders ()

Resets all the stablished headers

public Phalcon\Http\ResponseInterface setExpires (unknown \$datetime)

Sets a Expires header to use HTTP cache

```
<?php  
  
$this->response->setExpires(new DateTime());
```

public Phalcon\Http\ResponseInterface setNotModified ()

Sends a Not-Modified response

public Phalcon\Http\ResponseInterface setContentType (unknown \$contentType, [unknown \$charset])

Sets the response content-type mime, optionally the charset

```
<?php  
  
$response->setContentType('application/pdf');  
$response->setContentType('text/plain', 'UTF-8');
```

public Phalcon\Http\ResponseInterface setEtag (unknown \$etag)

Set a custom ETag

```
<?php  
  
$response->setEtag(md5(time()));
```

public Phalcon\Http\ResponseInterface redirect ([unknown \$location], [unknown \$externalRedirect], [unknown \$statusCode])

Redirect by HTTP to another action or URL

```
<?php  
  
//Using a string redirect (internal/external)  
$response->redirect("posts/index");  
$response->redirect("http://en.wikipedia.org", true);  
$response->redirect("http://www.example.com/new-location", true, 301);  
  
//Making a redirection based on a named route  
$response->redirect(array(  
    "for" => "index-lang",  
    "lang" => "jp",  
    "controller" => "index"  
));
```

public Phalcon\Http\ResponseInterface setContent (unknown \$content)

Sets HTTP response body

```
<?php  
  
response->setContent("<h1>Hello!</h1>");
```

`public Phalcon\Http\ResponseInterface setJsonContent (unknown $content, [unknown $jsonOptions])`

Sets HTTP response body. The parameter is automatically converted to JSON

```
<?php  
  
$response->setJsonContent (array ("status" => "OK")) ;
```

`public Phalcon\Http\ResponseInterface appendContent (unknown $content)`

Appends a string to the HTTP response body

`public string getContent ()`

Gets the HTTP response body

`public boolean isSent ()`

Check if the response is already sent

`public Phalcon\Http\ResponseInterface sendHeaders ()`

Sends headers to the client

`public Phalcon\Http\ResponseInterface sendCookies ()`

Sends cookies to the client

`public Phalcon\Http\ResponseInterface send ()`

Prints out HTTP response to the client

`public Phalcon\Http\ResponseInterface setFileToSend (unknown $filePath, [unknown $attachmentName], [unknown $attachment])`

Sets an attached file to be sent at the end of the request

2.58.112 Class Phalcon\Http\Response\Cookies

implements Phalcon\Http\Response\CookiesInterface, Phalcon\Di\InjectionAwareInterface

This class is a bag to manage the cookies A cookies bag is automatically registered as part of the ‘response’ service in the DI

Methods

`public setDI (unknown $dependencyInjector)`

Sets the dependency injector

`public Phalcon\DiInterface getDI ()`

Returns the internal dependency injector

`public Phalcon\Http\Response\Cookies useEncryption (unknown $useEncryption)`

Set if cookies in the bag must be automatically encrypted/decrypted

`public boolean isUsingEncryption ()`

Returns if the bag is automatically encrypting/decrypting cookies

`public Phalcon\Http\Response\Cookies set (unknown $name, [unknown $value], [unknown $expire], [unknown $path], [unknown $secure], [unknown $domain], [unknown $httpOnly])`

Sets a cookie to be sent at the end of the request This method overrides any cookie set before with the same name

public `Phalcon\Http\Cookie` **get** (*unknown \$name*)

Gets a cookie from the bag

public `boolean` **has** (*unknown \$name*)

Check if a cookie is defined in the bag or exists in the _COOKIE superglobal

public `boolean` **delete** (*unknown \$name*)

Deletes a cookie by its name This method does not removes cookies from the _COOKIE superglobal

public `boolean` **send** ()

Sends the cookies to the client Cookies aren't sent if headers are sent in the current request

public `Phalcon\Http\Response\Cookies` **reset** ()

Reset set cookies

2.58.113 Class Phalcon\Http\Response\Exception

extends class `Phalcon\Exception`

Methods

final private `Exception` **__clone** () inherited from `Exception`

Clone the exception

public **__construct** ([*string \$message*], [*int \$code*], [*Exception \$previous*]) inherited from `Exception`

Exception constructor

final public `string` **getMessage** () inherited from `Exception`

Gets the Exception message

final public `int` **getCode** () inherited from `Exception`

Gets the Exception code

final public `string` **getFile** () inherited from `Exception`

Gets the file in which the exception occurred

final public `int` **getLine** () inherited from `Exception`

Gets the line in which the exception occurred

final public `array` **getTrace** () inherited from `Exception`

Gets the stack trace

final public `Exception` **getPrevious** () inherited from `Exception`

Returns previous Exception

final public `Exception` **getTraceAsString** () inherited from `Exception`

Gets the stack trace as a string

public `string` **__toString** () inherited from `Exception`

String representation of the exception

2.58.114 Class Phalcon\Http\Response\Headers

implements Phalcon\Http\Response\HeadersInterface

This class is a bag to manage the response headers

Methods

public set (*unknown \$name, unknown \$value*)

Sets a header to be sent at the end of the request

public string get (*unknown \$name*)

Gets a header value from the internal bag

public setRaw (*unknown \$header*)

Sets a raw header to be sent at the end of the request

public remove (*unknown \$header*)

Removes a header to be sent at the end of the request

public boolean send ()

Sends the headers to the client

public reset ()

Reset set headers

public array toArray ()

Returns the current headers as an array

public static Phalcon\Http\Response\Headers __set_state (*unknown \$data*)

Restore a Phalcon\Http\Response\Headers object

2.58.115 Class Phalcon\Image

Constants

integer **NONE**

integer **WIDTH**

integer **HEIGHT**

integer **AUTO**

integer **INVERSE**

integer **PRECISE**

integer **TENSILE**

integer **HORIZONTAL**

integer **VERTICAL**

2.58.116 Abstract class Phalcon\Image\Adapter

Phalcon\Image All image adapters must use this class

Methods

public **getImage** ()

...

public **getRealpath** ()

...

public **getWidth** ()

Image width

public **getHeight** ()

Image height

public **getType** ()

Image type Driver dependent

public **getMime** ()

Image mime type

public **resize** ([*unknown \$width*], [*unknown \$height*], [*unknown \$master*])

Resize the image to the given size

public **liquidRescale** (*unknown \$width*, *unknown \$height*, *unknown \$deltaX*, *unknown \$rigidity*)

This method scales the images using liquid rescaling method. Only support Imagick

public **crop** (*unknown \$width*, *unknown \$height*, [*unknown \$offsetX*], [*unknown \$offsetY*])

Crop an image to the given size

public **rotate** (*unknown \$degrees*)

Rotate the image by a given amount

public **flip** (*unknown \$direction*)

Flip the image along the horizontal or vertical axis

public **sharpen** (*unknown \$amount*)

Sharpen the image by a given amount

public **reflection** (*unknown \$height*, [*unknown \$opacity*], [*unknown \$fadeIn*])

Add a reflection to an image

public **watermark** (*unknown \$watermark*, [*unknown \$offsetX*], [*unknown \$offsetY*], [*unknown \$opacity*])

Add a watermark to an image with a specified opacity

public **text** (*unknown \$text*, [*unknown \$offsetX*], [*unknown \$offsetY*], [*unknown \$opacity*], [*unknown \$color*], [*unknown \$size*], [*unknown \$fontfile*])

Add a text to an image with a specified opacity

public **mask** (*unknown \$watermark*)

Composite one image onto another

public `background` (*unknown* \$color, [*unknown* \$opacity])

Set the background color of an image

public `blur` (*unknown* \$radius)

Blur image

public `pixelate` (*unknown* \$amount)

Pixelate image

public `save` ([*unknown* \$file], [*unknown* \$quality])

Save the image

public `render` ([*unknown* \$ext], [*unknown* \$quality])

Render the image and return the binary string

2.58.117 Class Phalcon\Image\Adapter\Imagick

extends abstract class [Phalcon\Image\Adapter](#)

implements [Phalcon\Image\AdapterInterface](#)

Image manipulation support. Allows images to be resized, cropped, etc.

```
<?php

$image = new Phalcon\Image\Adapter\Imagick("upload/test.jpg");
$image->resize(200, 200)->rotate(90)->crop(100, 100);
if ($image->save()) {
    echo 'success';
}
```

Methods

public static boolean `check` ()

Checks if Imagick is enabled

public __construct (*unknown* \$file, [*unknown* \$width], [*unknown* \$height])

\Phalcon\Image\Imagick constructor

protected _resize (*unknown* \$width, *unknown* \$height)

Execute a resize.

protected _liquidRescale (*unknown* \$width, *unknown* \$height, *unknown* \$deltaX, *unknown* \$rigidity)

This method scales the images using liquid rescaling method. Only support Imagick

protected _crop (*unknown* \$width, *unknown* \$height, *unknown* \$offsetX, *unknown* \$offsetY)

Execute a crop.

protected _rotate (*unknown* \$degrees)

Execute a rotation.

protected _flip (*unknown* \$direction)

Execute a flip.

protected **_sharpen** (*unknown \$amount*)

Execute a sharpen.

protected **_reflection** (*unknown \$height*, *unknown \$opacity*, *unknown \$fadeIn*)

Execute a reflection.

protected **_watermark** (*unknown \$image*, *unknown \$offsetX*, *unknown \$offsetY*, *unknown \$opacity*)

Execute a watermarking.

protected **_text** (*unknown \$text*, *unknown \$offsetX*, *unknown \$offsetY*, *unknown \$opacity*, *unknown \$r*, *unknown \$g*, *unknown \$b*, *unknown \$size*, *unknown \$fontfile*)

Execute a text

protected **_mask** (*unknown \$image*)

Composite one image onto another

protected **_background** (*unknown \$r*, *unknown \$g*, *unknown \$b*, *unknown \$opacity*)

Execute a background.

protected **_blur** (*unknown \$radius*)

Blur image

protected **_pixelate** (*unknown \$amount*)

Pixelate image

protected **_save** (*unknown \$file*, *unknown \$quality*)

Execute a save.

protected **_render** (*unknown \$extension*, *unknown \$quality*)

Execute a render.

public **__destruct** ()

Destroys the loaded image to free up resources.

public **getInternalImInstance** ()

Get instance

public **setResourceLimit** (*unknown \$type*, *unknown \$limit*)

Sets the limit for a particular resource in megabytes

public **getImage** () inherited from Phalcon\Image\Adapter

...

public **getRealpath** () inherited from Phalcon\Image\Adapter

...

public **getWidth** () inherited from Phalcon\Image\Adapter

Image width

public **getHeight** () inherited from Phalcon\Image\Adapter

Image height

public **getType** () inherited from Phalcon\Image\Adapter

Image type Driver dependent

public **getMime** () inherited from Phalcon\Image\Adapter

Image mime type

public **resize** (*unknown \$width*, *unknown \$height*, *unknown \$master*) inherited from Phalcon\Image\Adapter

Resize the image to the given size

public **liquidRescale** (*unknown \$width*, *unknown \$height*, *unknown \$deltaX*, *unknown \$rigidity*) inherited from Phalcon\Image\Adapter

This method scales the images using liquid rescaling method. Only support Imagick

public **crop** (*unknown \$width*, *unknown \$height*, *unknown \$offsetX*, *unknown \$offsetY*) inherited from Phalcon\Image\Adapter

Crop an image to the given size

public **rotate** (*unknown \$degrees*) inherited from Phalcon\Image\Adapter

Rotate the image by a given amount

public **flip** (*unknown \$direction*) inherited from Phalcon\Image\Adapter

Flip the image along the horizontal or vertical axis

public **sharpen** (*unknown \$amount*) inherited from Phalcon\Image\Adapter

Sharpen the image by a given amount

public **reflection** (*unknown \$height*, *unknown \$opacity*, *unknown \$fadeIn*) inherited from Phalcon\Image\Adapter

Add a reflection to an image

public **watermark** (*unknown \$watermark*, *unknown \$offsetX*, *unknown \$offsetY*, *unknown \$opacity*) inherited from Phalcon\Image\Adapter

Add a watermark to an image with a specified opacity

public **text** (*unknown \$text*, *unknown \$offsetX*, *unknown \$offsetY*, *unknown \$opacity*, *unknown \$color*, *unknown \$size*, *unknown \$fontfile*) inherited from Phalcon\Image\Adapter

Add a text to an image with a specified opacity

public **mask** (*unknown \$watermark*) inherited from Phalcon\Image\Adapter

Composite one image onto another

public **background** (*unknown \$color*, *unknown \$opacity*) inherited from Phalcon\Image\Adapter

Set the background color of an image

public **blur** (*unknown \$radius*) inherited from Phalcon\Image\Adapter

Blur image

public **pixelate** (*unknown \$amount*) inherited from Phalcon\Image\Adapter

Pixelate image

public **save** (*unknown \$file*, *unknown \$quality*) inherited from Phalcon\Image\Adapter

Save the image

public **render** (*unknown \$ext*, *unknown \$quality*) inherited from Phalcon\Image\Adapter

Render the image and return the binary string

2.58.118 Class Phalcon\Image\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception

Gets the stack trace as a string

public *string* **__toString** () inherited from Exception

String representation of the exception

2.58.119 Class Phalcon\Kernel

Methods

public static **preComputeHashKey** (*unknown* \$key)

...

2.58.120 Class Phalcon\Loader

implements `Phalcon\Events\EventsAwareInterface`

This component helps to load your project classes automatically based on some conventions

```
<?php

//Creates the autoloader
$loader = new Loader();

//Register some namespaces
$loader->registerNamespaces(array(
    'Example\Base' => 'vendor/example/base/',
    'Example\Adapter' => 'vendor/example/adapter/',
    'Example' => 'vendor/example/'
));

//register autoloader
$loader->register();

//Requiring this class will automatically include file vendor/example/adapter/Some.php
$adapter = Example\Adapter\Some();
```

Methods

`public __construct ()`

Phalcon\Loader constructor

`public setEventsManager (unknown $eventsManager)`

Sets the events manager

`public Phalcon\Events\ManagerInterface getEventsManager ()`

Returns the internal event manager

`public Phalcon\Loader setExtensions (unknown $extensions)`

Sets an array of extensions that the loader must try in each attempt to locate the file

`public boolean getExtensions ()`

Return file extensions registered in the loader

`public Phalcon\Loader registerNamespaces (unknown $namespaces, [unknown $merge])`

Register namespaces and their related directories

`public getNamespaces ()`

Return current namespaces registered in the autoloader

`public Phalcon\Loader registerPrefixes (unknown $prefixes, [unknown $merge])`

Register directories on which “not found” classes could be found

`public getPrefixes ()`

Return current prefixes registered in the autoloader

`public Phalcon\Loader registerDirs (unknown $directories, [unknown $merge])`

Register directories on which “not found” classes could be found

```
public getDirs ()  
Return current directories registered in the autoloader  
public Phalcon\Loader registerClasses (unknown $classes, [unknown $merge])  
Register classes and their locations  
public getClasses ()  
Return the current class-map registered in the autoloader  
public Phalcon\Loader register ()  
Register the autoload method  
public Phalcon\Loader unregister ()  
Unregister the autoload method  
public boolean autoLoad (unknown $className)  
Makes the work of autoload registered classes  
public string getFoundPath ()  
Get the path when a class was found  
public string getCheckedPath ()  
Get the path the loader is checking for a path
```

2.58.121 Class Phalcon\Loader\Exception

extends class Phalcon\Exception

Methods

```
final private Exception __clone () inherited from Exception  
Clone the exception  
public __construct ([string $message], [int $code], [Exception $previous]) inherited from Exception  
Exception constructor  
final public string getMessage () inherited from Exception  
Gets the Exception message  
final public int getCode () inherited from Exception  
Gets the Exception code  
final public string getFile () inherited from Exception  
Gets the file in which the exception occurred  
final public int getLine () inherited from Exception  
Gets the line in which the exception occurred  
final public array getTrace () inherited from Exception  
Gets the stack trace  
final public Exception getPrevious () inherited from Exception
```

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from *Exception*

Gets the stack trace as a string

public *string* **_toString** () inherited from *Exception*

String representation of the exception

2.58.122 Abstract class Phalcon\Logger

Constants

integer **SPECIAL**

integer **CUSTOM**

integer **DEBUG**

integer **INFO**

integer **NOTICE**

integer **WARNING**

integer **ERROR**

integer **ALERT**

integer **CRITICAL**

integer **EMERGENCE**

integer **EMERGENCY**

2.58.123 Abstract class Phalcon\Logger\Adapter

Base class for Phalcon\Logger adapters

Methods

public **setLogLevel** (*unknown* \$level)

Filters the logs sent to the handlers that are less or equal than a specific level

public **getLogLevel** ()

Returns the current log level

public **setFormatter** (*unknown* \$formatter)

Sets the message formatter

public **begin** ()

Starts a transaction

public **commit** ()

Commits the internal transaction

public **rollback** ()

Rollbacks the internal transaction

public **critical** (*unknown* \$message, [*unknown* \$context])

Sends/Writes a critical message to the log

public **emergency** (*unknown* \$message, [*unknown* \$context])

Sends/Writes an emergency message to the log

public **debug** (*unknown* \$message, [*unknown* \$context])

Sends/Writes a debug message to the log

public **error** (*unknown* \$message, [*unknown* \$context])

Sends/Writes an error message to the log

public **info** (*unknown* \$message, [*unknown* \$context])

Sends/Writes an info message to the log

public **notice** (*unknown* \$message, [*unknown* \$context])

Sends/Writes a notice message to the log

public **warning** (*unknown* \$message, [*unknown* \$context])

Sends/Writes a warning message to the log

public **alert** (*unknown* \$message, [*unknown* \$context])

Sends/Writes an alert message to the log

public **log** (*unknown* \$type, [*unknown* \$message], [*unknown* \$context])

Logs messages to the internal logger. Appends logs to the logger

2.58.124 Class Phalcon\Logger\Adapter\File

extends abstract class [Phalcon\Logger\Adapter](#)

implements [Phalcon\Logger\AdapterInterface](#)

Adapter to store logs in plain text files

```
<?php

$logger = new \Phalcon\Logger\Adapter\File("app/logs/test.log");
$logger->log("This is a message");
$logger->log("This is an error", \Phalcon\Logger::ERROR);
$logger->error("This is another error");
$logger->close();
```

Methods

public **getPath** ()

File Path

public **__construct** (*unknown* \$name, [*unknown* \$options])

Phalcon\Logger\Adapter\File constructor

public [Phalcon\Logger\FormatterInterface](#) **getFormatter** ()

Returns the internal formatter

public `logInternal` (*unknown* \$message, *unknown* \$type, *unknown* \$time, *array* \$context)

Writes the log to the file itself

public `boolean close` ()

Closes the logger

public `__wakeup` ()

Opens the internal file handler after unserialization

public `setLogLevel` (*unknown* \$level) inherited from Phalcon\Logger\Adapter

Filters the logs sent to the handlers that are less or equal than a specific level

public `getLogLevel` () inherited from Phalcon\Logger\Adapter

Returns the current log level

public `setFormatter` (*unknown* \$formatter) inherited from Phalcon\Logger\Adapter

Sets the message formatter

public `begin` () inherited from Phalcon\Logger\Adapter

Starts a transaction

public `commit` () inherited from Phalcon\Logger\Adapter

Commits the internal transaction

public `rollback` () inherited from Phalcon\Logger\Adapter

Rollbacks the internal transaction

public `critical` (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a critical message to the log

public `emergency` (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an emergency message to the log

public `debug` (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a debug message to the log

public `error` (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an error message to the log

public `info` (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an info message to the log

public `notice` (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a notice message to the log

public `warning` (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a warning message to the log

public `alert` (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an alert message to the log

public `log` (*unknown* \$type, [*unknown* \$message], [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Logs messages to the internal logger. Appends logs to the logger

2.58.125 Class Phalcon\Logger\Adapter\Firephp

extends abstract class [Phalcon\Logger\Adapter](#)

implements [Phalcon\Logger\AdapterInterface](#)

Sends logs to FirePHP

```
<?php  
  
$logger = new \Phalcon\Logger\Adapter\Firephp("");  
$logger->log(\Phalcon\Logger::ERROR, "This is an error");  
$logger->error("This is another error");
```

Methods

public [Phalcon\Logger\FormatterInterface](#) **getFormatter** ()

Returns the internal formatter

public **logInternal** (*string* \$message, *int* \$type, *int* \$time, *array* \$context)

Writes the log to the stream itself

public *boolean* **close** ()

Closes the logger

public **setLogLevel** (*unknown* \$level) inherited from [Phalcon\Logger\Adapter](#)

Filters the logs sent to the handlers that are less or equal than a specific level

public **getLogLevel** () inherited from [Phalcon\Logger\Adapter](#)

Returns the current log level

public **setFormatter** (*unknown* \$formatter) inherited from [Phalcon\Logger\Adapter](#)

Sets the message formatter

public **begin** () inherited from [Phalcon\Logger\Adapter](#)

Starts a transaction

public **commit** () inherited from [Phalcon\Logger\Adapter](#)

Commits the internal transaction

public **rollback** () inherited from [Phalcon\Logger\Adapter](#)

Rollbacks the internal transaction

public **critical** (*unknown* \$message, [*unknown* \$context]) inherited from [Phalcon\Logger\Adapter](#)

Sends/Writes a critical message to the log

public **emergency** (*unknown* \$message, [*unknown* \$context]) inherited from [Phalcon\Logger\Adapter](#)

Sends/Writes an emergency message to the log

public **debug** (*unknown* \$message, [*unknown* \$context]) inherited from [Phalcon\Logger\Adapter](#)

Sends/Writes a debug message to the log

public `error` (*unknown \$message, [unknown \$context]*) inherited from Phalcon\Logger\Adapter
 Sends/Writes an error message to the log

public `info` (*unknown \$message, [unknown \$context]*) inherited from Phalcon\Logger\Adapter
 Sends/Writes an info message to the log

public `notice` (*unknown \$message, [unknown \$context]*) inherited from Phalcon\Logger\Adapter
 Sends/Writes a notice message to the log

public `warning` (*unknown \$message, [unknown \$context]*) inherited from Phalcon\Logger\Adapter
 Sends/Writes a warning message to the log

public `alert` (*unknown \$message, [unknown \$context]*) inherited from Phalcon\Logger\Adapter
 Sends/Writes an alert message to the log

public `log` (*unknown \$type, [unknown \$message], [unknown \$context]*) inherited from Phalcon\Logger\Adapter
 Logs messages to the internal logger. Appends logs to the logger

2.58.126 Class Phalcon\Logger\Adapter\Stream

extends abstract class Phalcon\Logger\Adapter

implements Phalcon\Logger\AdapterInterface

Sends logs to a valid PHP stream

```
<?php

$logger = new \Phalcon\Logger\Adapter\Stream("php://stderr");
$logger->log("This is a message");
$logger->log("This is an error", \Phalcon\Logger::ERROR);
$logger->error("This is another error");
```

Methods

public `__construct` (*unknown \$name, [unknown \$options]*)

Phalcon\Logger\Adapter\Stream constructor

public `Phalcon\Logger\Formatter\Line getFormatter` ()

Returns the internal formatter

public `logInternal` (*unknown \$message, unknown \$type, unknown \$time, array \$context*)

Writes the log to the stream itself

public `boolean close` ()

Closes the logger

public `setLogLevel` (*unknown \$level*) inherited from Phalcon\Logger\Adapter

Filters the logs sent to the handlers that are less or equal than a specific level

public `getLogLevel` () inherited from Phalcon\Logger\Adapter

Returns the current log level

public **setFormatter** (*unknown* \$formatter) inherited from Phalcon\Logger\Adapter

Sets the message formatter

public **begin** () inherited from Phalcon\Logger\Adapter

Starts a transaction

public **commit** () inherited from Phalcon\Logger\Adapter

Commits the internal transaction

public **rollback** () inherited from Phalcon\Logger\Adapter

Rollbacks the internal transaction

public **critical** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a critical message to the log

public **emergency** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an emergency message to the log

public **debug** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a debug message to the log

public **error** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an error message to the log

public **info** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an info message to the log

public **notice** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a notice message to the log

public **warning** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a warning message to the log

public **alert** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an alert message to the log

public **log** (*unknown* \$type, [*unknown* \$message], [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Logs messages to the internal logger. Appends logs to the logger

2.58.127 Class Phalcon\Logger\Adapter\Syslog

extends abstract class Phalcon\Logger\Adapter

implements Phalcon\Logger\AdapterInterface

Sends logs to the system logger

```
<?php

$logger = new \Phalcon\Logger\Adapter\Syslog("ident", array(
    'option' => LOG_NDELAY,
    'facility' => LOG_MAIL
));
$logger->log("This is a message");
```

```
$logger->log("This is an error", \Phalcon\Logger::ERROR);
$logger->error("This is another error");
```

Methods

public **__construct** (*unknown* \$name, [*unknown* \$options])

Phalcon\Logger\Adapter\Syslog constructor

public **Phalcon\Logger\Formatter\Line getFormatter ()**

Returns the internal formatter

public **logInternal** (*unknown* \$message, *unknown* \$type, *unknown* \$time, *array* \$context)

Writes the log to the stream itself

public **boolean close ()**

Closes the logger

public **setLogLevel** (*unknown* \$level) inherited from Phalcon\Logger\Adapter

Filters the logs sent to the handlers that are less or equal than a specific level

public **getLogLevel ()** inherited from Phalcon\Logger\Adapter

Returns the current log level

public **setFormatter** (*unknown* \$formatter) inherited from Phalcon\Logger\Adapter

Sets the message formatter

public **begin ()** inherited from Phalcon\Logger\Adapter

Starts a transaction

public **commit ()** inherited from Phalcon\Logger\Adapter

Commits the internal transaction

public **rollback ()** inherited from Phalcon\Logger\Adapter

Rollbacks the internal transaction

public **critical** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a critical message to the log

public **emergency** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an emergency message to the log

public **debug** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a debug message to the log

public **error** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an error message to the log

public **info** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes an info message to the log

public **notice** (*unknown* \$message, [*unknown* \$context]) inherited from Phalcon\Logger\Adapter

Sends/Writes a notice message to the log

public **warning** (*unknown \$message*, [*unknown \$context*]) inherited from Phalcon\Logger\Adapter

Sends/Writes a warning message to the log

public **alert** (*unknown \$message*, [*unknown \$context*]) inherited from Phalcon\Logger\Adapter

Sends/Writes an alert message to the log

public **log** (*unknown \$type*, [*unknown \$message*], [*unknown \$context*]) inherited from Phalcon\Logger\Adapter

Logs messages to the internal logger. Appends logs to the logger

2.58.128 Class Phalcon\Logger\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string \$message*], [*int \$code*], [*Exception \$previous*]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception

Gets the stack trace as a string

public *string* **__toString** () inherited from Exception

String representation of the exception

2.58.129 Abstract class Phalcon\Logger\Formatter

This is a base class for logger formatters

Methods

public string **getTypeString** (*unknown* \$type)

Returns the string meaning of a logger constant

public interpolate (*string* \$message, [*array* \$context])

Interpolates context values into the message placeholders

2.58.130 Class Phalcon\Logger\Formatter\Firephp

extends abstract class [Phalcon\Logger\Formatter](#)

implements [Phalcon\Logger\FormatterInterface](#)

Formats messages so that they can be sent to FirePHP

Methods

public string **getTypeString** (*integer* \$type)

Returns the string meaning of a logger constant

public this **setShowBacktrace** ([*unknown* \$isShow])

Returns the string meaning of a logger constant

public boolean **getShowBacktrace** ()

Returns the string meaning of a logger constant

public this **enableLabels** ([*unknown* \$isEnabled])

Returns the string meaning of a logger constant

public boolean **labelsEnabled** ()

Returns the labels enabled

public string **format** (*string* \$message, *int* \$type, *int* \$timestamp, [*array* \$context])

Applies a format to a message before sending it to the log

public interpolate (*string* \$message, [*array* \$context]) inherited from [Phalcon\Logger\Formatter](#)

Interpolates context values into the message placeholders

2.58.131 Class Phalcon\Logger\Formatter\Json

extends abstract class [Phalcon\Logger\Formatter](#)

implements [Phalcon\Logger\FormatterInterface](#)

Formats messages using JSON encoding

Methods

`public string format (unknown $message, unknown $type, unknown $timestamp, [array $context])`

Applies a format to a message before sent it to the internal log

`public string getTypeString (unknown $type)` inherited from Phalcon\Logger\Formatter

Returns the string meaning of a logger constant

`public interpolate (string $message, [array $context])` inherited from Phalcon\Logger\Formatter

Interpolates context values into the message placeholders

2.58.132 Class Phalcon\Logger\Formatter\Line

extends abstract class Phalcon\Logger\Formatter

implements Phalcon\Logger\FormatterInterface

Formats messages using an one-line string

Methods

`public getDateFormat ()`

Default date format

`public setDateFormat (unknown $dateFormat)`

Default date format

`public getFormat ()`

Format applied to each message

`public setFormat (unknown $format)`

Format applied to each message

`public __construct ([unknown $format], [unknown $dateFormat])`

Phalcon\Logger\Formatter\Line construct

`public string format (unknown $message, unknown $type, unknown $timestamp, [array $context])`

Applies a format to a message before sent it to the internal log

`public string getTypeString (unknown $type)` inherited from Phalcon\Logger\Formatter

Returns the string meaning of a logger constant

`public interpolate (string $message, [array $context])` inherited from Phalcon\Logger\Formatter

Interpolates context values into the message placeholders

2.58.133 Class Phalcon\Logger\Formatter\Syslog

extends abstract class Phalcon\Logger\Formatter

implements Phalcon\Logger\FormatterInterface

Prepares a message to be used in a Syslog backend

Methods

public **array format** (*unknown \$message, unknown \$type, unknown \$timestamp, [array \$context]*)

Applies a format to a message before sent it to the internal log

public **string getTypeString** (*unknown \$type*) inherited from Phalcon\Logger\Formatter

Returns the string meaning of a logger constant

public **interpolate** (*string \$message, [array \$context]*) inherited from Phalcon\Logger\Formatter

Interpolates context values into the message placeholders

2.58.134 Class Phalcon\Logger\Item

Represents each item in a logging transaction

Methods

public **getType** ()

Log type

public **getMessage** ()

Log message

public **getTime** ()

Log timestamp

public **getContext** ()

...

public **__construct** (*string \$message, integer \$type, [integer \$time], [array \$context]*)

Phalcon\Logger\Item constructor

2.58.135 Class Phalcon\Logger\Multiple

Handles multiples logger handlers

Methods

public **getLoggers** ()

...

public **getFormatter** ()

...

public **push** (*unknown \$logger*)

Pushes a logger to the logger tail

public **setFormatter** (*unknown \$formatter*)

Sets a global formatter

public **log** (*unknown* \$message, [*unknown* \$type])

Sends a message to each registered logger

public **emergency** (*unknown* \$message)

Sends/Writes an emergency message to the log

public **debug** (*unknown* \$message)

Sends/Writes a debug message to the log

public **error** (*unknown* \$message)

Sends/Writes an error message to the log

public **info** (*unknown* \$message)

Sends/Writes an info message to the log

public **notice** (*unknown* \$message)

Sends/Writes a notice message to the log

public **warning** (*unknown* \$message)

Sends/Writes a warning message to the log

public **alert** (*unknown* \$message)

Sends/Writes an alert message to the log

2.58.136 Class Phalcon\\Mvc\\Application

extends abstract class Phalcon\\Di\\Injectable

implements Phalcon\\Events\\EventsAwareInterface, Phalcon\\Di\\InjectionAwareInterface

This component encapsulates all the complex operations behind instantiating every component needed and integrating it with the rest to allow the MVC pattern to operate as desired.

```
<?php

class Application extends \Phalcon\Mvc\Application
{

    /**
     * Register the services here to make them general or register
     * in the ModuleDefinition to make them module-specific
     */
    protected function _registerServices()
    {

    }

    /**
     * This method registers all the modules in the application
     */
    public function main()
    {
        $this->registerModules(array(
            'frontend' => array(
                'className' => 'Multiple\Frontend\Module',
                'path' => '../apps/frontend/Module.php'
            )
        ));
    }
}
```

```

        ),
        'backend' => array(
            'className' => 'Multiple\Backend\Module',
            'path' => '../apps/backend/Module.php'
        )
    ) );
}
}

$application = new Application();
$application->main();

```

Methods

public __construct ([*unknown* \$dependencyInjector])

public Phalcon\Mvc\Application useImplicitView (*unknown* \$implicitView)

By default, the view is implicitly buffering all the output. You can fully disable the view component using this method.

public registerModules (*unknown* \$modules, [*unknown* \$merge])

Register an array of modules present in the application

```
<?php

$this->registerModules(array(
    'frontend' => array(
        'className' => 'Multiple\Frontend\Module',
        'path' => '../apps/frontend/Module.php'
    ),
    'backend' => array(
        'className' => 'Multiple\Backend\Module',
        'path' => '../apps/backend/Module.php'
    )
));

```

public *array* getModules ()

Return the modules registered in the application

public *array|object* getModule (*unknown* \$name)

Gets the module definition registered in the application via module name

public Phalcon\Mvc\Application setDefaultModule (*unknown* \$defaultModule)

Sets the module name to be used if the router doesn't return a valid module

public *string* getDefaultModule ()

Returns the default module name

public Phalcon\Http\ResponseInterface |boolean handle ([*unknown* \$uri])

Handles a MVC request

public setDI (*unknown* \$dependencyInjector) inherited from Phalcon\Di\Injectable

Sets the dependency injector

public Phalcon\DiInterface getDI () inherited from Phalcon\Di\Injectable

Returns the internal dependency injector

public **setEventsManager** (*unknown* \$eventsManager) inherited from Phalcon\Di\Injectable

Sets the event manager

public Phalcon\Events\ManagerInterface **getEventsManager** () inherited from Phalcon\Di\Injectable

Returns the internal event manager

public **__get** (*unknown* \$propertyName) inherited from Phalcon\Di\Injectable

Magic method **__get**

2.58.137 Class Phalcon\Mvc\Application\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception

Gets the stack trace as a string

public *string* **__toString** () inherited from Exception

String representation of the exception

2.58.138 Abstract class Phalcon\Mvc\Collection

implements Phalcon\Mvc\CollectionInterface, Phalcon\Di\InjectionAwareInterface, Serializable

This component implements a high level abstraction for NoSQL databases which works with documents

Constants

integer **OP_NONE**

integer **OP_CREATE**

integer **OP_UPDATE**

integer **OP_DELETE**

Methods

final public __construct ([*unknown* \$dependencyInjector], [*unknown* \$modelsManager])

Phalcon\Mvc\Model constructor

public **setId** (*unknown* \$id)

Sets a value for the _id property, creates a MongoId object if needed

public *MongoId* **getId** ()

Returns the value of the _id property

public **setDI** (*unknown* \$dependencyInjector)

Sets the dependency injection container

public *Phalcon\DiInterface* **getDI** ()

Returns the dependency injection container

protected **setEventsManager** (*unknown* \$eventsManager)

Sets a custom events manager

protected *Phalcon\Events\ManagerInterface* **getEventsManager** ()

Returns the custom events manager

public *Phalcon\Mvc\Model\ManagerInterface* **getCollectionManager** ()

Returns the models manager related to the entity instance

public *array* **getReservedAttributes** ()

Returns an array with reserved properties that cannot be part of the insert/update

protected **useImplicitObjectIds** (*unknown* \$useImplicitObjectIds)

Sets if a model must use implicit objects ids

protected *Phalcon\Mvc\Collection* **setSource** (*unknown* \$source)

Sets collection name which model should be mapped

public *string* **getSource** ()

Returns collection name mapped in the model

public *Phalcon\Mvc\Model* **setConnectionService** (*unknown* \$connectionService)

Sets the DependencyInjection connection service name

public *string* **getConnectionService** ()

Returns DependencyInjection connection service

public *MongoDb* **getConnection** ()

Retrieves a database connection

public *mixed* **readAttribute** (*unknown* \$attribute)

Reads an attribute value by its name

```
<?php  
  
echo robot->readAttribute('name');
```

public **writeAttribute** (*unknown* \$attribute, *unknown* \$value)

Writes an attribute value by its name

```
<?php  
  
robot->writeAttribute('name', 'Rosey');
```

public static **Phalcon\Mvc\Collection** **cloneResult** (*unknown* \$collection, *unknown* \$document)

Returns a cloned collection

protected static *array* **_getResultSet** (*unknown* \$params, *unknown* \$collection, *unknown* \$connection, *unknown* \$unique)

Returns a collection resultset

protected static *int* **_getGroupResultSet** (*unknown* \$params, *unknown* \$collection, *unknown* \$connection)

Perform a count over a resultset

final protected *boolean* **_preSave** (*unknown* \$dependencyInjector, *unknown* \$disableEvents, *unknown* \$exists)

Executes internal hooks before save a document

final protected *boolean* **_postSave** (*unknown* \$disableEvents, *unknown* \$success, *unknown* \$exists)

Executes internal events after save a document

protected **validate** (*unknown* \$validator)

Executes validators on every validation call

```
<?php  
  
use Phalcon\Mvc\Model\Validator\ExclusionIn as ExclusionIn;  
  
class Subscribers extends \Phalcon\Mvc\Collection  
{  
  
    public function validation()  
    {  
        this->validate(new ExclusionIn(array(  
            'field' => 'status',  
            'domain' => array('A', 'I')  
        ));  
        if (this->validationHasFailed() == true) {  
            return false;  
        }  
    }  
}
```

public *boolean* **validationHasFailed** ()

Check whether validation process has generated any messages

```
<?php

use Phalcon\Mvc\Model\Validator\ExclusionIn as ExclusionIn;

class Subscribers extends \Phalcon\Mvc\Collection
{

public function validation()
{
    $this->validate(new ExclusionIn(array(
        'field' => 'status',
        'domain' => array('A', 'I')
    )));
    if ($this->validationHasFailed() == true) {
        return false;
    }
}
}
```

`public boolean fireEvent (unknown $eventName)`

Fires an internal event

`public boolean fireEventCancel (unknown $eventName)`

Fires an internal event that cancels the operation

`protected boolean _cancelOperation (unknown $disableEvents)`

Cancel the current operation

`protected boolean _exists (unknown $collection)`

Checks if the document exists in the collection

`public Phalcon\Mvc\Model\MessageInterface [] getMessages ()`

Returns all the validation messages

```
<?php

robot = new Robots();
robot->type = 'mechanical';
robot->name = 'Astro Boy';
robot->year = 1952;
if (robot->save() == false) {
echo "Umh, We can't store robots right now ";
foreach (robot->getMessages() as message) {
    echo message;
}
} else {
echo "Great, a new robot was saved successfully!";
}
```

`public appendMessage (unknown $message)`

Appends a customized message on the validation process

```
<?php
```

```
use \Phalcon\Mvc\Model\Message as Message;

class Robots extends \Phalcon\Mvc\Model
{

    public function beforeSave()
    {
        if ($this->name == 'Peter') {
            $message = new Message("Sorry, but a robot cannot be named Peter");
            $this->appendMessage($message);
        }
    }
}
```

public boolean save ()

Creates/Updates a collection based on the values in the attributes

public static Phalcon\Mvc\Collection findById (*unknown* \$id)

Find a document by its id (_id)

public static array findFirst ([*unknown* \$parameters])

Allows to query the first record that match the specified conditions

```
<?php

//What's the first robot in the robots table?
$robot = Robots::findFirst();
echo "The robot name is ", $robot->name, "\n";

//What's the first mechanical robot in robots table?
$robot = Robots::findFirst(array(
    'array("type" => "mechanical")
));
echo "The first mechanical robot name is ", $robot->name, "\n";

//Get first virtual robot ordered by name
$robot = Robots::findFirst(array(
    'array("type" => "mechanical"),
    "order" => array("name" => 1)
));
echo "The first virtual robot name is ", $robot->name, "\n";
```

public static array find ([*unknown* \$parameters])

Allows to query a set of records that match the specified conditions

```
<?php

//How many robots are there?
$robots = Robots::find();
echo "There are ", count($robots), "\n";

//How many mechanical robots are there?
$robots = Robots::find(array(
    'array("type" => "mechanical")
));
echo "There are ", count($robots), "\n";
```

```
//Get and print virtual robots ordered by name
robots = Robots::findFirst(array(
    array("type" => "virtual"),
    "order" => array("name" => 1)
));
foreach (robots as robot) {
    echo robot->name, "\n";
}

//Get first 100 virtual robots ordered by name
robots = Robots::find(array(
    array("type" => "virtual"),
    "order" => array("name" => 1),
    "limit" => 100
));
foreach (robots as robot) {
    echo robot->name, "\n";
}
```

public static array count ([*unknown \$parameters*])

Perform a count over a collection

```
<?php
echo 'There are ', Robots::count(), ' robots';
```

public static array aggregate (*unknown \$parameters*)

Perform an aggregation using the Mongo aggregation framework

public static array summaratory (*unknown \$field*, [*unknown \$conditions*], [*unknown \$finalize*])

Allows to perform a summatory group for a column in the collection

public boolean delete ()

Deletes a model instance. Returning true on success or false otherwise.

```
<?php
robot = Robots::findFirst();
robot->delete();

foreach (Robots::find() as robot) {
    robot->delete();
}
```

public array toArray ()

Returns the instance as an array representation

```
<?php
print_r(robot->to[]);
```

public string serialize ()

Serializes the object ignoring connections or protected properties

public unserialize (*unknown \$data*)

Unserializes the object from a serialized string

2.58.139 Class Phalcon\\Mvc\\Collection\\Document

implements ArrayAccess

This component allows Phalcon\\Mvc\\Collection to return rows without an associated entity. This objects implements the ArrayAccess interface to allow access the object as object->x or array[x].

Methods

public *boolean* offsetExists (*unknown* \$index)

Checks whether an offset exists in the document

public *mixed* offsetGet (*unknown* \$index)

Returns the value of a field using the ArrayAccess interfase

public offsetSet (*unknown* \$index, *unknown* \$value)

Change a value using the ArrayAccess interface

public offsetUnset (*unknown* \$offset)

Rows cannot be changed. It has only been implemented to meet the definition of the ArrayAccess interface

public *mixed* readAttribute (*unknown* \$attribute)

Reads an attribute value by its name

```
<?php
```

```
echo robot->readAttribute('name');
```

public writeAttribute (*unknown* \$attribute, *unknown* \$value)

Writes an attribute value by its name

```
<?php
```

```
robot->writeAttribute('name', 'Rosey');
```

2.58.140 Class Phalcon\\Mvc\\Collection\\Exception

extends class Phalcon\\Exception

Methods

final private *Exception* __clone () inherited from Exception

Clone the exception

public __construct ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* getMessage () inherited from Exception

Gets the Exception message

final public *int* getCode () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception
Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception
Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception
Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception
Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception
Gets the stack trace as a string

public *string* **__toString** () inherited from Exception
String representation of the exception

2.58.141 Class Phalcon\Mvc\Collection\Manager

implements Phalcon\Di\InjectionAwareInterface, Phalcon\Events\EventsAwareInterface

This components controls the initialization of models, keeping record of relations between the different models of the application. A CollectionManager is injected to a model via a Dependency Injector Container such as Phalcon\Di.

```
<?php

$di = new \Phalcon\Di();

$di->set('collectionManager', function(){
    return new \Phalcon\Mvc\Collection\Manager();
});

$robot = new Robots($di);
```

Methods

public **setDI** (Phalcon\DiInterface \$dependencyInjector)
Sets the DependencyInjector container

public Phalcon\DiInterface **getDI** ()
Returns the DependencyInjector container

public **setEventsManager** (Phalcon\Events\ManagerInterface \$eventsManager)
Sets the event manager

public Phalcon\Events\ManagerInterface **getEventsManager** ()
Returns the internal event manager

public **setCustomEventsManager** (Phalcon\Mvc\CollectionInterface \$model, Phalcon\Events\ManagerInterface \$eventsManager)
Sets a custom events manager for a specific model

public `Phalcon\Events\ManagerInterface` **getCustomEventsManager** (`Phalcon\Mvc\CollectionInterface $model`)
Returns a custom events manager related to a model

public **initialize** (*unknown* `$model`)
Initializes a model in the models manager

public *bool* **isInitialized** (`string $modelName`)
Check whether a model is already initialized

public `Phalcon\Mvc\CollectionInterface` **getLastInitialized** ()
Get the latest initialized model

public **setConnectionService** (*unknown* `$model`, *unknown* `$connectionService`)
Sets a connection service for a specific model

public **useImplicitObjectIds** (*unknown* `$model`, *unknown* `$useImplicitObjectIds`)
Sets whether a model must use implicit objects ids

public *boolean* **isUsingImplicitObjectIds** (*unknown* `$model`)
Checks if a model is using implicit object ids

public *Mongo* **getConnection** (`Phalcon\Mvc\CollectionInterface $model`)
Returns the connection related to a model

public **notifyEvent** (*unknown* `$eventName`, *unknown* `$model`)
Receives events generated in the models and dispatches them to a events-manager if available Notify the behaviors that are listening in the model

2.58.142 Abstract class Phalcon\Mvc\Controller

extends abstract class `Phalcon\Di\Injectable`

implements `Phalcon\Events\EventsAwareInterface`, `Phalcon\Di\InjectionAwareInterface`

Every application controller should extend this class that encapsulates all the controller functionality. The controllers provide the “flow” between models and views. Controllers are responsible for processing the incoming requests from the web browser, interrogating the models for data, and passing that data on to the views for presentation.

```
<?php  
  
<?php  
  
class PeopleController extends \Phalcon\Mvc\Controller  
{  
  
    //This action will be executed by default  
    public function indexAction()  
    {  
  
    }  
  
    public function findAction()  
    {  
  
    }  
}
```

```

public function saveAction()
{
    //Forwards flow to the index action
    return $this->dispatcher->forward(array('controller' => 'people', 'action' => 'index'));
}

```

Methods

final public __construct ()

Phalcon\Mvc\Controller constructor

public setDI (unknown \$dependencyInjector) inherited from Phalcon\Di\Injectable

Sets the dependency injector

public Phalcon\DiInterface getDI () inherited from Phalcon\Di\Injectable

Returns the internal dependency injector

public setEventsManager (unknown \$eventsManager) inherited from Phalcon\Di\Injectable

Sets the event manager

public Phalcon\Events\ManagerInterface getEventsManager () inherited from Phalcon\Di\Injectable

Returns the internal event manager

public __get (unknown \$propertyName) inherited from Phalcon\Di\Injectable

Magic method __get

2.58.143 Class Phalcon\Mvc\Dispatcher

extends abstract class Phalcon\Dispatcher

implements Phalcon\Events\EventsAwareInterface, Phalcon\Di\InjectionAwareInterface, Phalcon\DispatcherInterface, Phalcon\Mvc\DispatcherInterface

Dispatching is the process of taking the request object, extracting the module name, controller name, action name, and optional parameters contained in it, and then instantiating a controller and calling an action of that controller.

```

<?php

$di = new \Phalcon\Di();

$dispatcher = new \Phalcon\Mvc\Dispatcher();

$dispatcher->setDI($di);

$dispatcher->setControllerName('posts');
$dispatcher->setActionName('index');
$dispatcher->setParams(array());

$controller = $dispatcher->dispatch();

```

Constants

integer **EXCEPTION_NO_DI**
integer **EXCEPTION_CYCLIC_ROUTING**
integer **EXCEPTION_HANDLER_NOT_FOUND**
integer **EXCEPTION_INVALID_HANDLER**
integer **EXCEPTION_INVALID_PARAMS**
integer **EXCEPTION_ACTION_NOT_FOUND**

Methods

public **setControllerSuffix** (*unknown* \$controllerSuffix)
Sets the default controller suffix

public **setDefaultController** (*unknown* \$controllerName)
Sets the default controller name

public **setControllerName** (*unknown* \$controllerName)
Sets the controller name to be dispatched

public *string* **getControllerName** ()
Gets last dispatched controller name

public *string* **getPreviousControllerName** ()
Gets previous dispatched controller name

public *string* **getPreviousActionName** ()
Gets previous dispatched action name

protected **_throwDispatchException** (*unknown* \$message, [*unknown* \$exceptionCode])
Throws an internal exception

protected **_handleException** (*unknown* \$exception)
Handles a user exception

public *string* **getControllerClass** ()
Possible controller class name that will be located to dispatch the request

public [Phalcon\Mvc\ControllerInterface](#) **getLastController** ()
Returns the lastest dispatched controller

public [Phalcon\Mvc\ControllerInterface](#) **getActiveController** ()
Returns the active controller in the dispatcher

public **__construct** () inherited from [Phalcon\Dispatcher](#)
Phalcon\Dispatcher constructor

public **setDI** (*unknown* \$dependencyInjector) inherited from [Phalcon\Dispatcher](#)
Sets the dependency injector

public [Phalcon\DiInterface](#) **getDI** () inherited from [Phalcon\Dispatcher](#)

Returns the internal dependency injector

public `setEventsManager` (*unknown* \$eventsManager) inherited from Phalcon\Dispatcher

Sets the events manager

public `Phalcon\Events\ManagerInterface getEventsManager` () inherited from Phalcon\Dispatcher

Returns the internal event manager

public `setActionSuffix` (*unknown* \$actionSuffix) inherited from Phalcon\Dispatcher

Sets the default action suffix

public `setModuleName` (*unknown* \$moduleName) inherited from Phalcon\Dispatcher

Sets the module where the controller is (only informative)

public `string getModuleName` () inherited from Phalcon\Dispatcher

Gets the module where the controller class is

public `setNamespaceName` (*unknown* \$namespaceName) inherited from Phalcon\Dispatcher

Sets the namespace where the controller class is

public `string getNamespaceName` () inherited from Phalcon\Dispatcher

Gets a namespace to be prepended to the current handler name

public `setDefaultNamespace` (*unknown* \$namespaceName) inherited from Phalcon\Dispatcher

Sets the default namespace

public `string getDefaultNamespace` () inherited from Phalcon\Dispatcher

Returns the default namespace

public `setDefaultAction` (*unknown* \$actionName) inherited from Phalcon\Dispatcher

Sets the default action name

public `setActionName` (*unknown* \$actionName) inherited from Phalcon\Dispatcher

Sets the action name to be dispatched

public `string getActionName` () inherited from Phalcon\Dispatcher

Gets the latest dispatched action name

public `setParams` (*unknown* \$params) inherited from Phalcon\Dispatcher

Sets action params to be dispatched

public `array getParams` () inherited from Phalcon\Dispatcher

Gets action params

public `setParam` (*unknown* \$param, *unknown* \$value) inherited from Phalcon\Dispatcher

Set a param by its name or numeric index

public `mixedgetParam` (*unknown* \$param, [*unknown* \$filters], [*unknown* \$defaultValue]) inherited from Phalcon\Dispatcher

Gets a param by its name or numeric index

public `string getActiveMethod` () inherited from Phalcon\Dispatcher

Returns the current method to be/executed in the dispatcher

public *boolean* **isFinished** () inherited from Phalcon\Dispatcher

Checks if the dispatch loop is finished or has more pendent controllers/tasks to dispatch

public **setReturnedValue** (*unknown* \$value) inherited from Phalcon\Dispatcher

Sets the latest returned value by an action manually

public *mixed* **getReturnValue** () inherited from Phalcon\Dispatcher

Returns value returned by the lastest dispatched action

public *object* **dispatch** () inherited from Phalcon\Dispatcher

Dispatches a handle action taking into account the routing parameters

public **forward** (*unknown* \$forward) inherited from Phalcon\Dispatcher

Forwards the execution flow to another controller/action Dispatchers are unique per module. Forwarding between modules is not allowed

```
<?php
```

```
$this->dispatcher->forward(array("controller" => "posts", "action" => "index"));
```

public *boolean* **wasForwarded** () inherited from Phalcon\Dispatcher

Check if the current executed action was forwarded by another one

2.58.144 Class Phalcon\Mvc\Dispatcher\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from *Exception*

Gets the stack trace as a string

public *string* **__toString** () inherited from *Exception*

String representation of the exception

2.58.145 Class Phalcon\Mvc\Micro

extends abstract class *Phalcon\Di\Injectable*

implements *Phalcon\Events\EventsAwareInterface*, *Phalcon\Di\InjectionAwareInterface*, *ArrayAccess*

With Phalcon you can create “Micro-Framework like” applications. By doing this, you only need to write a minimal amount of code to create a PHP application. Micro applications are suitable to small applications, APIs and prototypes in a practical way.

```
<?php

$app = new \Phalcon\Mvc\Micro();

$app->get('/say/welcome/{name}', function ($name) {
    echo "<h1>Welcome $name!</h1>";
});

$app->handle();
```

Methods

public **__construct** ([*Phalcon\DiInterface* *\$dependencyInjector*])

Phalcon\Mvc\Micro constructor

public **setDI** (*unknown* *\$dependencyInjector*)

Sets the *DependencyInjector* container

public *Phalcon\Mvc\Router\RouteInterface* **map** (*unknown* *\$routePattern*, *unknown* *\$handler*)

Maps a route to a handler without any HTTP method constraint

public *Phalcon\Mvc\Router\RouteInterface* **get** (*unknown* *\$routePattern*, *unknown* *\$handler*)

Maps a route to a handler that only matches if the HTTP method is GET

public *Phalcon\Mvc\Router\RouteInterface* **post** (*unknown* *\$routePattern*, *unknown* *\$handler*)

Maps a route to a handler that only matches if the HTTP method is POST

public *Phalcon\Mvc\Router\RouteInterface* **put** (*string* *\$routePattern*, *callable* *\$handler*)

Maps a route to a handler that only matches if the HTTP method is PUT

public *Phalcon\Mvc\Router\RouteInterface* **patch** (*string* *\$routePattern*, *callable* *\$handler*)

Maps a route to a handler that only matches if the HTTP method is PATCH

public *Phalcon\Mvc\Router\RouteInterface* **head** (*unknown* *\$routePattern*, *unknown* *\$handler*)

Maps a route to a handler that only matches if the HTTP method is HEAD

public *Phalcon\Mvc\Router\RouteInterface* **delete** (*unknown* *\$routePattern*, *unknown* *\$handler*)

Maps a route to a handler that only matches if the HTTP method is DELETE

public **Phalcon\Mvc\Router\RouteInterface** **options** (*unknown* \$routePattern, *unknown* \$handler)

Maps a route to a handler that only matches if the HTTP method is OPTIONS

public **Phalcon\Mvc\Micro** **mount** (*unknown* \$collection)

Mounts a collection of handlers

public **Phalcon\Mvc\Micro** **notFound** (*unknown* \$handler)

Sets a handler that will be called when the router doesn't match any of the defined routes

public **Phalcon\Mvc\Micro** **error** (*unknown* \$handler)

Sets a handler that will be called when an exception is thrown handling the route

public **Phalcon\Mvc\RouterInterface** **getRouter** ()

Returns the internal router used by the application

public **Phalcon\DI\ServiceInterface** **setService** (*unknown* \$serviceName, *unknown* \$definition, [*unknown* \$shared])

Sets a service from the DI

public *boolean* **hasService** (*unknown* \$serviceName)

Checks if a service is registered in the DI

public *object* **getService** (*unknown* \$serviceName)

Obtains a service from the DI

public *mixed* **getSharedService** (*unknown* \$serviceName)

Obtains a shared service from the DI

public *mixed* **handle** ([*unknown* \$uri])

Handle the whole request

public **stop** ()

Stops the middleware execution avoiding than other middlewares be executed

public **setActiveHandler** (*unknown* \$activeHandler)

Sets externally the handler that must be called by the matched route

public *callable* **getActiveHandler** ()

Return the handler that will be called for the matched route

public *mixed* **getReturnValue** ()

Returns the value returned by the executed handler

public *boolean* **offsetExists** (*unknown* \$alias)

Check if a service is registered in the internal services container using the array syntax

public **offsetSet** (*unknown* \$alias, *unknown* \$definition)

Allows to register a shared service in the internal services container using the array syntax

```
<?php  
  
$app['request'] = new \Phalcon\Http\Request();
```

public mixed offsetGet (*unknown* \$alias)

Allows to obtain a shared service in the internal services container using the array syntax

```
<?php
var_dump($di['request']);
```

public offsetUnset (*unknown* \$alias)

Removes a service from the internal services container using the array syntax

public Phalcon\Mvc\Micro before (*unknown* \$handler)

Appends a before middleware to be called before execute the route

public Phalcon\Mvc\Micro after (*unknown* \$handler)

Appends an ‘after’ middleware to be called after execute the route

public Phalcon\Mvc\Micro finish (*unknown* \$handler)

Appends a ‘finish’ middleware to be called when the request is finished

public array getHandlers ()

Returns the internal handlers attached to the application

public Phalcon\DiInterface getDI () inherited from Phalcon\Di\Injectable

Returns the internal dependency injector

public setEventsManager (*unknown* \$eventsManager) inherited from Phalcon\Di\Injectable

Sets the event manager

public Phalcon\Events\ManagerInterface getEventsManager () inherited from Phalcon\Di\Injectable

Returns the internal event manager

public __get (*unknown* \$propertyName) inherited from Phalcon\Di\Injectable

Magic method __get

2.58.146 Class Phalcon\Mvc\Micro\Collection

implements Phalcon\Mvc\Micro\CollectionInterface

Groups Micro-Mvc handlers as controllers

```
<?php
$app = new \Phalcon\Mvc\Micro();
$collection = new Collection();
$collection->setHandler(new PostsController());
$collection->get('/posts/edit/{id}', 'edit');
$app->mount($collection);
```

Methods

private **_addMap** (*unknown* \$method, *unknown* \$routePattern, *unknown* \$handler, *unknown* \$name)

Internal function to add a handler to the group

public **Phalcon\Mvc\Micro\Collection setPrefix** (*unknown* \$prefix)

Sets a prefix for all routes added to the collection

public **string getPrefix** ()

Returns the collection prefix if any

public **array getHandlers** ()

Returns the registered handlers

public **Phalcon\Mvc\Micro\Collection setHandler** (*unknown* \$handler, [*unknown* \$lazy])

Sets the main handler

public **Phalcon\Mvc\Micro\Collection setLazy** (*unknown* \$lazy)

Sets if the main handler must be lazy loaded

public **boolean isLazy** ()

Returns if the main handler must be lazy loaded

public **mixed getHandler** ()

Returns the main handler

public **Phalcon\Mvc\Micro\Collection map** (*unknown* \$routePattern, *unknown* \$handler, [*unknown* \$name])

Maps a route to a handler

public **Phalcon\Mvc\Micro\Collection get** (*unknown* \$routePattern, *unknown* \$handler, [*unknown* \$name])

Maps a route to a handler that only matches if the HTTP method is GET

public **Phalcon\Mvc\Micro\Collection post** (*unknown* \$routePattern, *unknown* \$handler, [*unknown* \$name])

Maps a route to a handler that only matches if the HTTP method is POST

public **Phalcon\Mvc\Micro\Collection put** (*unknown* \$routePattern, *unknown* \$handler, [*unknown* \$name])

Maps a route to a handler that only matches if the HTTP method is PUT

public **Phalcon\Mvc\Micro\Collection patch** (*unknown* \$routePattern, *unknown* \$handler, [*unknown* \$name])

Maps a route to a handler that only matches if the HTTP method is PATCH

public **Phalcon\Mvc\Micro\Collection head** (*unknown* \$routePattern, *unknown* \$handler, [*unknown* \$name])

Maps a route to a handler that only matches if the HTTP method is HEAD

public **Phalcon\Mvc\Micro\Collection delete** (*unknown* \$routePattern, *unknown* \$handler, [*unknown* \$name])

Maps a route to a handler that only matches if the HTTP method is DELETE

public **Phalcon\Mvc\Micro\Collection options** (*unknown* \$routePattern, *unknown* \$handler, [*unknown* \$name])

Maps a route to a handler that only matches if the HTTP method is OPTIONS

2.58.147 Class Phalcon\Mvc\Micro\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from *Exception*
Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from *Exception*
Exception constructor

final public *string* **getMessage** () inherited from *Exception*
Gets the *Exception* message

final public *int* **getCode** () inherited from *Exception*
Gets the *Exception* code

final public *string* **getFile** () inherited from *Exception*
Gets the file in which the *exception* occurred

final public *int* **getLine** () inherited from *Exception*
Gets the line in which the *exception* occurred

final public *array* **getTrace** () inherited from *Exception*
Gets the stack trace

final public *Exception* **getPrevious** () inherited from *Exception*
Returns previous *Exception*

final public *Exception* **getTraceAsString** () inherited from *Exception*
Gets the stack trace as a string

public *string* **__toString** () inherited from *Exception*
String representation of the *exception*

2.58.148 Class Phalcon\Mvc\Micro\LazyLoader

Lazy-Load of handlers for *Mvc\Micro* using auto-loading

Methods

public **__construct** (*unknown* \$definition)
Phalcon\Mvc\Micro\LazyLoader constructor

public *mixed* **__call** (*unknown* \$method, *unknown* \$arguments)
Initializes the internal handler, calling functions on it

2.58.149 Abstract class Phalcon\Mvc\Model

implements *Phalcon\Mvc\ModelInterface*, *Phalcon\Mvc\Model\ResultInterface*, *Phalcon\Di\InjectionAwareInterface*, *Serializable*

Phalcon\Mvc\Model connects business objects and database tables to create a persistable domain model where logic and data are presented in one wrapping. It's an implementation of the object-relational mapping (ORM). A model

represents the information (data) of the application and the rules to manipulate that data. Models are primarily used for managing the rules of interaction with a corresponding database table. In most cases, each table in your database will correspond to one model in your application. The bulk of your application's business logic will be concentrated in the models. Phalcon\Mvc\Model is the first ORM written in C-language for PHP, giving to developers high performance when interacting with databases while is also easy to use.

```
<?php

$robot = new Robots();
$robot->type = 'mechanical';
$robot->name = 'Astro Boy';
$robot->year = 1952;
if ($robot->save() == false) {
    echo "Umh, We can store robots: ";
    foreach ($robot->getMessages() as $message) {
        echo message;
    }
} else {
    echo "Great, a new robot was saved successfully!";
}
```

Constants

integer **OP_NONE**
integer **OP_CREATE**
integer **OP_UPDATE**
integer **OP_DELETE**
integer **DIRTY_STATE_PERSISTENT**
integer **DIRTY_STATE_TRANSIENT**
integer **DIRTY_STATE_DETACHED**

Methods

final public __construct ([*unknown* \$dependencyInjector], [*unknown* \$modelsManager])

Phalcon\Mvc\Model constructor

public setDI (*unknown* \$dependencyInjector)

Sets the dependency injection container

public Phalcon\DiInterface getDI ()

Returns the dependency injection container

protected setEventsManager (*unknown* \$eventsManager)

Sets a custom events manager

protected Phalcon\Events\ManagerInterface getEventsManager ()

Returns the custom events manager

public Phalcon\Mvc\Model\MetaDataInterface getModelsMetaData ()

Returns the models meta-data service related to the entity instance

public Phalcon\Mvc\Model\ManagerInterface getModelsManager ()

Returns the models manager related to the entity instance

public Phalcon\Mvc\Model setTransaction (Phalcon\Mvc\Model\TransactionInterface \$transaction)

Sets a transaction related to the Model instance

```
<?php

use Phalcon\Mvc\Model\Transaction\Manager as TxManager;
use Phalcon\Mvc\Model\Transaction\Failed as TxFailed;

try {

    $txManager = new TxManager();

    $transaction = $txManager->get();

    $robot = new Robots();
    $robot->setTransaction($transaction);
    $robot->name = 'WALL·E';
    $robot->created_at = date('Y-m-d');
    if ($robot->save() == false) {
        $transaction->rollback("Can't save robot");
    }

    $robotPart = new RobotParts();
    $robotPart->setTransaction($transaction);
    $robotPart->type = 'head';
    if ($robotPart->save() == false) {
        $transaction->rollback("Robot part cannot be saved");
    }

    $transaction->commit();

} catch (TxFailed $e) {
    echo 'Failed, reason: ', $e->getMessage();
}
```

protected Phalcon\Mvc\Model setSource (*unknown* \$source)

Sets table name which model should be mapped

public string getSource ()

Returns table name mapped in the model

protected Phalcon\Mvc\Model setSchema (*unknown* \$schema)

Sets schema name where table mapped is located

public string getSchema ()

Returns schema name where table mapped is located

public Phalcon\Mvc\Model setConnectionService (*unknown* \$connectionService)

Sets the DependencyInjection connection service name

public Phalcon\Mvc\Model setReadConnectionService (*unknown* \$connectionService)

Sets the DependencyInjection connection service name used to read data

public Phalcon\Mvc\Model setWriteConnectionService (*unknown* \$connectionService)

Sets the DependencyInjection connection service name used to write data

public string getReadConnectionService ()

Returns the DependencyInjection connection service name used to read data related the model

public string getWriteConnectionService ()

Returns the DependencyInjection connection service name used to write data related to the model

public Phalcon\Mvc\Model setDirtyState (unknown \$dirtyState)

Sets the dirty state of the object using one of the DIRTY_STATE_* constants

public int getDirtyState ()

Returns one of the DIRTY_STATE_* constants telling if the record exists in the database or not

public Phalcon\Db\AdapterInterface getReadConnection ()

Gets the connection used to read data for the model

public Phalcon\Db\AdapterInterface getWriteConnection ()

Gets the connection used to write data to the model

public Phalcon\Mvc\Model assign (unknown \$data, [unknown \$dataColumnMap], [unknown \$whiteList])

Assigns values to a model from an array

```
<?php

$robot->assign(array(
    'type' => 'mechanical',
    'name' => 'Astro Boy',
    'year' => 1952
));

//assign by db row, column map needed
$robot->assign($dbRow, array(
    'db_type' => 'type',
    'db_name' => 'name',
    'db_year' => 'year'
));

//allow assign only name and year
$robot->assign($_POST, null, array('name', 'year'));
```

public static Phalcon\Mvc\Model cloneResultMap (unknown \$base, unknown \$data, unknown \$columnMap, [unknown \$dirtyState], [unknown \$keepSnapshots])

Assigns values to a model from an array returning a new model.

```
<?php

$robot = \Phalcon\Mvc\Model::cloneResultMap(new Robots(), array(
    'type' => 'mechanical',
    'name' => 'Astro Boy',
    'year' => 1952
));
```

public static mixed cloneResultMapHydrate (unknown \$data, unknown \$columnMap, unknown \$hydrationMode)

Returns an hydrated result based on the data and the column map

public static Phalcon\Mvc\ModelInterface **cloneResult** (Phalcon\Mvc\ModelInterface \$base, *unknown* \$data, [*unknown* \$dirtyState])

Assigns values to a model from an array returning a new model

```
<?php

$robot = Phalcon\Mvc\Model::cloneResult(new Robots(), array(
    'type' => 'mechanical',
    'name' => 'Astro Boy',
    'year' => 1952
));
```

public static Phalcon\Mvc\Model\ResultsetInterface **find** ([*unknown* \$parameters])

Allows to query a set of records that match the specified conditions

```
<?php

//How many robots are there?
$robots = Robots::find();
echo "There are ", count($robots), "\n";

//How many mechanical robots are there?
$robots = Robots::find("type='mechanical'");
echo "There are ", count($robots), "\n";

//Get and print virtual robots ordered by name
$robots = Robots::find(array("type='virtual'", "order" => "name"));
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}

//Get first 100 virtual robots ordered by name
$robots = Robots::find(array("type='virtual'", "order" => "name", "limit" => 100));
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}
```

public static Phalcon\Mvc\Model **findFirst** ([*unknown* \$parameters])

Allows to query the first record that match the specified conditions

```
<?php

//What's the first robot in robots table?
$robot = Robots::findFirst();
echo "The robot name is ", $robot->name;

//What's the first mechanical robot in robots table?
$robot = Robots::findFirst("type='mechanical'");
echo "The first mechanical robot name is ", $robot->name;

//Get first virtual robot ordered by name
$robot = Robots::findFirst(array("type='virtual'", "order" => "name"));
echo "The first virtual robot name is ", $robot->name;
```

public static Phalcon\Mvc\Model\Criteria **query** ([*unknown* \$dependencyInjector])

Create a criteria for a specific model

protected *boolean* **_exists** (*unknown* \$metaData, *unknown* \$connection, [*unknown* \$table])

Checks if the current record already exists or not

protected static `Phalcon\Mvc\Model\ResultsetInterface` `_groupResult` (*unknown* \$functionName, *unknown* \$alias, *unknown* \$parameters)

Generate a PHQL SELECT statement for an aggregate

public static *mixed* `count` ([*unknown* \$parameters])

Allows to count how many records match the specified conditions

```
<?php

//How many robots are there?
$number = Robots:::count();
echo "There are ", $number, "\n";

//How many mechanical robots are there?
$number = Robots:::count("type='mechanical'");
echo "There are ", $number, " mechanical robots\n";
```

public static *mixed* `sum` ([*unknown* \$parameters])

Allows to calculate a summatory on a column that match the specified conditions

```
<?php

//How much are all robots?
$sum = Robots:::sum(array('column' => 'price'));
echo "The total price of robots is ", $sum, "\n";

//How much are mechanical robots?
$sum = Robots:::sum(array("type='mechanical'", 'column' => 'price'));
echo "The total price of mechanical robots is ", $sum, "\n";
```

public static *mixed* `maximum` ([*unknown* \$parameters])

Allows to get the maximum value of a column that match the specified conditions

```
<?php

//What is the maximum robot id?
$id = Robots:::maximum(array('column' => 'id'));
echo "The maximum robot id is: ", $id, "\n";

//What is the maximum id of mechanical robots?
$sum = Robots:::maximum(array("type='mechanical'", 'column' => 'id'));
echo "The maximum robot id of mechanical robots is ", $id, "\n";
```

public static *mixed* `minimum` ([*unknown* \$parameters])

Allows to get the minimum value of a column that match the specified conditions

```
<?php

//What is the minimum robot id?
$id = Robots:::minimum(array('column' => 'id'));
echo "The minimum robot id is: ", $id;

//What is the minimum id of mechanical robots?
$sum = Robots:::minimum(array("type='mechanical'", 'column' => 'id'));
echo "The minimum robot id of mechanical robots is ", $id;
```

public static *double* **average** ([*unknown* \$parameters])

Allows to calculate the average value on a column matching the specified conditions

```
<?php

//What's the average price of robots?
$average = Robots:::average(array('column' => 'price'));
echo "The average price is ", $average, "\n";

//What's the average price of mechanical robots?
$average = Robots:::average(array("type='mechanical'", 'column' => 'price'));
echo "The average price of mechanical robots is ", $average, "\n";
```

public *boolean* **fireEvent** (*unknown* \$eventName)

Fires an event, implicitly calls behaviors and listeners in the events manager are notified

public *boolean* **fireEventCancel** (*unknown* \$eventName)

Fires an event, implicitly calls behaviors and listeners in the events manager are notified This method stops if one of the callbacks/listeners returns boolean false

protected **_cancelOperation** ()

Cancel the current operation

public Phalcon\Mvc\Model **appendMessage** (*unknown* \$message)

Appends a customized message on the validation process

```
<?php

use \Phalcon\Mvc\Model\Message as Message;

class Robots extends \Phalcon\Mvc\Model
{

    public function beforeSave()
    {
        if ($this->name == 'Peter') {
            $message = new Message("Sorry, but a robot cannot be named Peter");
            $this->appendMessage($message);
        }
    }
}
```

protected Phalcon\Mvc\Model **validate** (*unknown* \$validator)

Executes validators on every validation call

```
<?php

use Phalcon\Mvc\Model\Validator\ExclusionIn as ExclusionIn;

class Subscribers extends \Phalcon\Mvc\Model
{

    public function validation()
    {
        $this->validate(new ExclusionIn(array(
            'field' => 'status',
            'domain' => array('A', 'I')
        ))
    }
}
```

```

        }));
    if ($this->validationHasFailed() == true) {
        return false;
    }
}
}

```

public boolean validationHasFailed ()

Check whether validation process has generated any messages

```
<?php

use Phalcon\Mvc\Model\Validator\ExclusionIn as ExclusionIn;

class Subscribers extends \Phalcon\Mvc\Model
{

public function validation()
{
    $this->validate(new ExclusionIn(array(
        'field' => 'status',
        'domain' => array('A', 'I')
    )));
    if ($this->validationHasFailed() == true) {
        return false;
    }
}

}
```

public Phalcon\Mvc\Model\MessageInterface [] getMessages ([unknown \$filter])

Returns all the validation messages

```
<?php

$robot = new Robots();
$robot->type = 'mechanical';
$robot->name = 'Astro Boy';
$robot->year = 1952;
if ($robot->save() == false) {
    echo "Umh, We can't store robots right now ";
    foreach ($robot->getMessages() as $message) {
        echo $message;
    }
} else {
    echo "Great, a new robot was saved successfully!";
}
```

protected boolean _checkForeignKeysRestrict ()

Reads “belongs to” relations and check the virtual foreign keys when inserting or updating records to verify that inserted/updated values are present in the related entity

protected boolean _checkForeignKeysReverseCascade ()

Reads both “hasMany” and “hasOne” relations and checks the virtual foreign keys (cascade) when deleting records

protected boolean _checkForeignKeysReverseRestrict ()

Reads both “hasMany” and “hasOne” relations and checks the virtual foreign keys (restrict) when deleting records

protected boolean _preSave (unknown \$metaData, unknown \$exists, unknown \$identityField)

Executes internal hooks before save a record

protected boolean _postSave (unknown \$success, unknown \$exists)

Executes internal events after save a record

protected boolean _doLowInsert (unknown \$metaData, unknown \$connection, unknown \$table, unknown \$identityField)

Sends a pre-build INSERT SQL statement to the relational database system

protected boolean _doLowUpdate (unknown \$metaData, unknown \$connection, unknown \$table)

Sends a pre-build UPDATE SQL statement to the relational database system

protected boolean _preSaveRelatedRecords (unknown \$connection, unknown \$related)

Saves related records that must be stored prior to save the master record

protected boolean _postSaveRelatedRecords (unknown \$connection, unknown \$related)

Save the related records assigned in the has-one/has-many relations

public boolean save ([unknown \$data], [unknown \$whiteList])

Inserts or updates a model instance. Returning true on success or false otherwise.

```
<?php

//Creating a new robot
$robot = new Robots();
$robot->type = 'mechanical';
$robot->name = 'Astro Boy';
$robot->year = 1952;
$robot->save();

//Updating a robot name
$robot = Robots::findFirst("id=100");
$robot->name = "Biomass";
$robot->save();
```

public boolean create ([unknown \$data], [unknown \$whiteList])

Inserts a model instance. If the instance already exists in the persistance it will throw an exception Returning true on success or false otherwise.

```
<?php

//Creating a new robot
$robot = new Robots();
$robot->type = 'mechanical';
$robot->name = 'Astro Boy';
$robot->year = 1952;
$robot->create();

//Passing an array to create
$robot = new Robots();
$robot->create(array(
    'type' => 'mechanical',
    'name' => 'Astro Boy',
```

```
'year' => 1952  
));
```

public boolean update ([*unknown* \$data], [*unknown* \$whiteList])

Updates a model instance. If the instance doesn't exist in the persistance it will throw an exception Returning true on success or false otherwise.

```
<?php  
  
//Updating a robot name  
$robot = Robots::findFirst("id=100");  
$robot->name = "Biomass";  
$robot->update();
```

public boolean delete ()

Deletes a model instance. Returning true on success or false otherwise.

```
<?php  
  
$robot = Robots::findFirst("id=100");  
$robot->delete();  
  
foreach (Robots::find("type = 'mechanical'") as $robot) {  
    $robot->delete();  
}
```

public int getOperationMade ()

Returns the type of the latest operation performed by the ORM Returns one of the OP_* class constants

public PhalconMvcModel refresh ()

Refreshes the model attributes re-querying the record from the database

public skipOperation (*unknown* \$skip)

Skips the current operation forcing a success state

public mixed readAttribute (*unknown* \$attribute)

Reads an attribute value by its name

```
<?php  
  
echo $robot->readAttribute('name');
```

public writeAttribute (*unknown* \$attribute, *unknown* \$value)

Writes an attribute value by its name

```
<?php  
  
$robot->writeAttribute('name', 'Rosey');
```

protected skipAttributes (*unknown* \$attributes)

Sets a list of attributes that must be skipped from the generated INSERT/UPDATE statement

```
<?php  
  
<?php
```

```
class Robots extends \Phalcon\Mvc\Model
{

    public function initialize()
    {
        $this->skipAttributes(array('price'));
    }

}
```

protected **skipAttributesOnCreate** (*unknown* \$attributes)

Sets a list of attributes that must be skipped from the generated INSERT statement

```
<?php

<?php

class Robots extends \Phalcon\Mvc\Model
{

    public function initialize()
    {
        $this->skipAttributesOnCreate(array('created_at'));
    }

}
```

protected **skipAttributesOnUpdate** (*unknown* \$attributes)

Sets a list of attributes that must be skipped from the generated UPDATE statement

```
<?php

<?php

class Robots extends \Phalcon\Mvc\Model
{

    public function initialize()
    {
        $this->skipAttributesOnUpdate(array('modified_in'));
    }

}
```

protected **Phalcon\Mvc\Model\Relation hasOne** (*unknown* \$fields, *unknown* \$referenceModel, *unknown* \$referencedFields, [*unknown* \$options])

Setup a 1-1 relation between two models

```
<?php

<?php

class Robots extends \Phalcon\Mvc\Model
{

    public function initialize()
    {
```

```

        $this->hasOne('id', 'RobotsDescription', 'robots_id');
    }

}

```

protected `Phalcon\Mvc\Model\Relation belongsTo` (*unknown* \$fields, *unknown* \$referenceModel, *unknown* \$referencedFields, [*unknown* \$options])

Setup a relation reverse 1-1 between two models

```

<?php

<?php

class RobotsParts extends \Phalcon\Mvc\Model
{

    public function initialize()
    {
        $this->belongsTo('robots_id', 'Robots', 'id');
    }

}

```

protected `Phalcon\Mvc\Model\Relation hasMany` (*unknown* \$fields, *unknown* \$referenceModel, *unknown* \$referencedFields, [*unknown* \$options])

Setup a relation 1-n between two models

```

<?php

<?php

class Robots extends \Phalcon\Mvc\Model
{

    public function initialize()
    {
        $this->hasMany('id', 'RobotsParts', 'robots_id');
    }

}

```

protected `Phalcon\Mvc\Model\Relation hasManyToMany` (*unknown* \$fields, *unknown* \$intermediateModel, *unknown* \$intermediateFields, *unknown* \$intermediateReferencedFields, *unknown* \$referenceModel, *unknown* \$referencedFields, [*unknown* \$options])

Setup a relation n-n between two models through an intermediate relation

```

<?php

<?php

class Robots extends \Phalcon\Mvc\Model
{

    public function initialize()
    {
        //Setup a many-to-many relation to Parts through RobotsParts
        $this->hasManyToMany(

```

```

        'id',
        'RobotsParts',
        'robots_id',
        'parts_id',
        'Parts',
        'id'
    );
}

}

```

protected addBehavior (*unknown* \$behavior)

Sets up a behavior in a model

```

<?php

<?php

use Phalcon\Mvc\Model\Behavior\Timestampable;

class Robots extends \Phalcon\Mvc\Model
{

    public function initialize()
    {
        $this->addBehavior(new Timestampable(array(
            'onCreate' => array(
                'field' => 'created_at',
                'format' => 'Y-m-d'
            )
        )));
    }

}

```

protected keepSnapshots (*unknown* \$keepSnapshot)

Sets if the model must keep the original record snapshot in memory

```

<?php

<?php

class Robots extends \Phalcon\Mvc\Model
{

    public function initialize()
    {
        $this->keepSnapshots(true);
    }

}

```

public setSnapshotData (*unknown* \$data, [*unknown* \$columnMap])

Sets the record's snapshot data. This method is used internally to set snapshot data when the model was set up to keep snapshot data

public boolean hasSnapshotData ()

Checks if the object has internal snapshot data

public array getSnapshotData ()

Returns the internal snapshot data

public boolean hasChanged ([*unknown* \$fieldName])

Check if a specific attribute has changed This only works if the model is keeping data snapshots

public array getChangedFields ()

Returns a list of changed values

protected boolean useDynamicUpdate (*unknown* \$dynamicUpdate)

Sets if a model must use dynamic update instead of the all-field update

```
<?php  
  
<?php  
  
class Robots extends \Phalcon\Mvc\Model  
{  
  
    public function initialize()  
    {  
        $this->useDynamicUpdate(true);  
    }  
  
}
```

public Phalcon\Mvc\Model\ResultsetInterface getRelated (*unknown* \$alias, [*unknown* \$arguments])

Returns related records based on defined relations

protected mixed _getRelatedRecords (*unknown* \$modelName, *unknown* \$method, *unknown* \$arguments)

Returns related records defined relations depending on the method name

public mixed __call (*unknown* \$method, [*unknown* \$arguments])

Handles method calls when a method is not implemented

public static mixed __callStatic (*unknown* \$method, [*unknown* \$arguments])

Handles method calls when a static method is not implemented

public __set (*unknown* \$property, *unknown* \$value)

Magic method to assign values to the the model

public Phalcon\Mvc\Model\Resultset |PhalconMvcModel __get (*unknown* \$property)

Magic method to get related records using the relation alias as a property

public boolean __isSet (*unknown* \$property)

Magic method to check if a property is a valid relation

public string serialize ()

Serializes the object ignoring connections, services, related objects or static properties

public unserialize (*unknown* \$data)

Unserializes the object from a serialized string

public array dump ()

Returns a simple representation of the object that can be used with var_dump

```
<?php
var_dump($robot->dump());
```

public array toArray ([array \$columns])

Returns the instance as an array representation

```
<?php
print_r($robot->toArray());
```

public static setup (unknown \$options)

Enables/disables options in the ORM

public reset ()

Reset a model instance data

2.58.150 Abstract class Phalcon\Mvc\Model\Behavior

This is an optional base class for ORM behaviors

Methods

public __construct ([unknown \$options])

protected mustTakeAction (unknown \$eventName)

Checks whether the behavior must take action on certain event

protected array getOptions ([unknown \$eventName])

Returns the behavior options related to an event

public notify (unknown \$type, unknown \$model)

This method receives the notifications from the EventsManager

public missingMethod (unknown \$model, unknown \$method, [unknown \$arguments])

Acts as fallbacks when a missing method is called on the model

2.58.151 Class Phalcon\Mvc\Model\Behavior\SoftDelete

extends abstract class Phalcon\Mvc\Model\Behavior

implements Phalcon\Mvc\Model\BehaviorInterface

Instead of permanently delete a record it marks the record as deleted changing the value of a flag column

Methods

public notify (unknown \$type, unknown \$model)

Listens for notifications from the models manager

public **__construct** (*unknown \$options*) inherited from Phalcon\Mvc\Model\Behavior
Phalcon\Mvc\Model\Behavior

protected **mustTakeAction** (*unknown \$eventName*) inherited from Phalcon\Mvc\Model\Behavior
Checks whether the behavior must take action on certain event

protected *array getOptions* (*unknown \$eventName*) inherited from Phalcon\Mvc\Model\Behavior
Returns the behavior options related to an event

public **missingMethod** (*unknown \$model*, *unknown \$method*, [*unknown \$arguments*]) inherited from Phalcon\Mvc\Model\Behavior
Acts as fallbacks when a missing method is called on the model

2.58.152 Class Phalcon\Mvc\Model\Behavior\Timestampable

extends abstract class Phalcon\Mvc\Model\Behavior
implements Phalcon\Mvc\Model\BehaviorInterface
Allows to automatically update a model's attribute saving the datetime when a record is created or updated

Methods

public **notify** (*unknown \$type*, *unknown \$model*)
Listens for notifications from the models manager

public **__construct** (*unknown \$options*) inherited from Phalcon\Mvc\Model\Behavior
Phalcon\Mvc\Model\Behavior

protected **mustTakeAction** (*unknown \$eventName*) inherited from Phalcon\Mvc\Model\Behavior
Checks whether the behavior must take action on certain event

protected *array getOptions* (*unknown \$eventName*) inherited from Phalcon\Mvc\Model\Behavior
Returns the behavior options related to an event

public **missingMethod** (*unknown \$model*, *unknown \$method*, [*unknown \$arguments*]) inherited from Phalcon\Mvc\Model\Behavior
Acts as fallbacks when a missing method is called on the model

2.58.153 Class Phalcon\Mvc\Model\Criteria

implements Phalcon\Mvc\Model\CriteriaInterface, Phalcon\Di\InjectionAwareInterface
This class is used to build the array parameter required by Phalcon\Mvc\Model::find() and Phalcon\Mvc\Model::findFirst() using an object-oriented interface.

```
<?php  
  
$robots = Robots::query()  
    ->where("type = :type:")  
    ->andWhere("year < 2000")  
    ->bind(array("type" => "mechanical"))  
    ->limit(5, 10)
```

```
->order("name")
->execute();
```

Methods

public `setDI` (*unknown* \$dependencyInjector)

Sets the DependencyInjector container

public `Phalcon\DiInterface getDI` ()

Returns the DependencyInjector container

public `Phalcon\Mvc\Model\Criteria set modelName` (*unknown* \$modelName)

Set a model on which the query will be executed

public `string getModelName` ()

Returns an internal model name on which the criteria will be applied

public `Phalcon\Mvc\Model\Criteria bind` (*unknown* \$bindParams)

Sets the bound parameters in the criteria This method replaces all previously set bound parameters

public `Phalcon\Mvc\Model\Criteria bindTypes` (*unknown* \$bindTypes)

Sets the bind types in the criteria This method replaces all previously set bound parameters

public `Phalcon\Mvc\Model\Criteria columns` (*unknown* \$columns)

Sets the columns to be queried

```
<?php
$criteria->columns(array('id', 'name'));
```

public `Phalcon\Mvc\Model\Criteria join` (*unknown* \$model, [*unknown* \$conditions], [*unknown* \$alias], [*unknown* \$type])

Adds a INNER join to the query

```
<?php
$criteria->join('Robots');
$criteria->join('Robots', 'r.id = RobotsParts.robots_id');
$criteria->join('Robots', 'r.id = RobotsParts.robots_id', 'r');
$criteria->join('Robots', 'r.id = RobotsParts.robots_id', 'r', 'LEFT');
```

public `Phalcon\Mvc\Model\Criteria innerJoin` (*unknown* \$model, [*unknown* \$conditions], [*unknown* \$alias])

Adds a INNER join to the query

```
<?php
$criteria->innerJoin('Robots');
$criteria->innerJoin('Robots', 'r.id = RobotsParts.robots_id');
$criteria->innerJoin('Robots', 'r.id = RobotsParts.robots_id', 'r');
```

public `Phalcon\Mvc\Model\Criteria leftJoin` (*unknown* \$model, [*unknown* \$conditions], [*unknown* \$alias])

Adds a LEFT join to the query

```
<?php
```

```
$criteria->leftJoin('Robots', 'r.id = RobotsParts.robots_id', 'r');
```

public `Phalcon\Mvc\Model\Criteria` **rightJoin** (*unknown* \$model, [*unknown* \$conditions], [*unknown* \$alias])

Adds a RIGHT join to the query

```
<?php
```

```
$criteria->rightJoin('Robots', 'r.id = RobotsParts.robots_id', 'r');
```

public `Phalcon\Mvc\Model\Criteria` **where** (*unknown* \$conditions, [*unknown* \$bindParams], [*unknown* \$bindTypes])

Sets the conditions parameter in the criteria

public `Phalcon\Mvc\Model\Criteria` **addWhere** (*unknown* \$conditions, [*unknown* \$bindParams], [*unknown* \$bindTypes])

Appends a condition to the current conditions using an AND operator (deprecated)

public `Phalcon\Mvc\Model\Criteria` **andWhere** (*unknown* \$conditions, [*unknown* \$bindParams], [*unknown* \$bindTypes])

Appends a condition to the current conditions using an AND operator

public `Phalcon\Mvc\Model\Criteria` **orWhere** (*unknown* \$conditions, [*unknown* \$bindParams], [*unknown* \$bindTypes])

Appends a condition to the current conditions using an OR operator

public `Phalcon\Mvc\Model\Criteria` **betweenWhere** (*unknown* \$expr, *unknown* \$minimum, *unknown* \$maximum)

Appends a BETWEEN condition to the current conditions

```
<?php
```

```
$criteria->betweenWhere('price', 100.25, 200.50);
```

public `Phalcon\Mvc\Model\Criteria` **notBetweenWhere** (*unknown* \$expr, *unknown* \$minimum, *unknown* \$maximum)

Appends a NOT BETWEEN condition to the current conditions

```
<?php
```

```
$criteria->notBetweenWhere('price', 100.25, 200.50);
```

public `Phalcon\Mvc\Model\Criteria` **inWhere** (*unknown* \$expr, *unknown* \$values)

Appends an IN condition to the current conditions

```
<?php
```

```
$criteria->inWhere('id', [1, 2, 3]);
```

public `Phalcon\Mvc\Model\Criteria` **notInWhere** (*unknown* \$expr, *unknown* \$values)

Appends a NOT IN condition to the current conditions

```
<?php
```

```
$criteria->notInWhere('id', [1, 2, 3]);
```

public `Phalcon\Mvc\Model\Criteria` **conditions** (*unknown* \$conditions)

Adds the conditions parameter to the criteria

public `Phalcon\Mvc\Model\Criteria` **order** (*unknown* \$orderColumns)

Adds the order-by parameter to the criteria (deprecated)

public `Phalcon\Mvc\Model\Criteria` **orderBy** (*unknown* \$orderColumns)

Adds the order-by parameter to the criteria

public `Phalcon\Mvc\Model\Criteria` **limit** (*unknown* \$limit, [*unknown* \$offset])

Adds the limit parameter to the criteria

public `Phalcon\Mvc\Model\Criteria` **forUpdate** ([*unknown* \$forUpdate])

Adds the “for_update” parameter to the criteria

public `Phalcon\Mvc\Model\Criteria` **sharedLock** ([*unknown* \$sharedLock])

Adds the “shared_lock” parameter to the criteria

public `Phalcon\Mvc\Model\Criteria` **cache** (*unknown* \$cache)

Sets the cache options in the criteria This method replaces all previously set cache options

public *string|null* **getWhere** ()

Returns the conditions parameter in the criteria

public *string|array|null* **getColumns** ()

Returns the columns to be queried

public *string|null* **getConditions** ()

Returns the conditions parameter in the criteria

public *int|array|null* **getLimit** ()

Returns the limit parameter in the criteria, which will be an integer if limit was set without an offset, an array with ‘number’ and ‘offset’ keys if an offset was set with the limit, or null if limit has not been set.

public *string|null* **getOrder** ()

Returns the order parameter in the criteria

public *array* **getParams** ()

Returns all the parameters defined in the criteria

public static `Phalcon\Mvc\Model\Criteria` **fromInput** (*unknown* \$dependencyInjector, *unknown* \$modelName, *unknown* \$data)

Builds a Phalcon\Mvc\Model\Criteria based on an input array like _POST

public `Phalcon\Mvc\Model\ResultsetInterface` **execute** ()

Executes a find using the parameters built with the criteria

2.58.154 Class `Phalcon\Mvc\Model\Exception`

extends class `Phalcon\Exception`

Methods

final private *Exception* **__clone** () inherited from *Exception*

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from *Exception*

Exception constructor

final public *string* **getMessage** () inherited from *Exception*

Gets the Exception message

final public *int* **getCode** () inherited from *Exception*

Gets the Exception code

final public *string* **getFile** () inherited from *Exception*

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from *Exception*

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from *Exception*

Gets the stack trace

final public *Exception* **getPrevious** () inherited from *Exception*

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from *Exception*

Gets the stack trace as a string

public *string* **__toString** () inherited from *Exception*

String representation of the exception

2.58.155 Class Phalcon\Mvc\Model\Manager

implements `Phalcon\Mvc\Model\ManagerInterface`, `Phalcon\Di\InjectionAwareInterface`, `Phalcon\Events\EventsAwareInterface`

This components controls the initialization of models, keeping record of relations between the different models of the application. A ModelsManager is injected to a model via a Dependency Injector/Services Container such as Phalcon\DI.

```
<?php

$di = new \Phalcon\DI();

$di->set('modelsManager', function() {
    return new \Phalcon\Mvc\Model\Manager();
});

$robot = new Robots($di);
```

Methods

public **setDI** (*unknown* \$dependencyInjector)

Sets the DependencyInjector container

public [Phalcon\DiInterface](#) **getDI** ()

Returns the DependencyInjector container

public **setEventsManager** (*unknown* \$eventsManager)

Sets a global events manager

public [Phalcon\Events\ManagerInterface](#) **getEventsManager** ()

Returns the internal event manager

public **setCustomEventsManager** (*unknown* \$model, *unknown* \$eventsManager)

Sets a custom events manager for a specific model

public [Phalcon\Events\ManagerInterface](#) **getCustomEventsManager** (*unknown* \$model)

Returns a custom events manager related to a model

public *boolean* **initialize** (*unknown* \$model)

Initializes a model in the model manager

public *bool* **isInitialized** (*unknown* \$modelName)

Check whether a model is already initialized

public [Phalcon\Mvc\ModelInterface](#) **getLastInitialized** ()

Get last initialized model

public [Phalcon\Mvc\ModelInterface](#) **load** (*unknown* \$modelName, [*unknown* \$newInstance])

Loads a model throwing an exception if it doesn't exist

public **setModelSource** (*unknown* \$model, *unknown* \$source)

Sets the mapped source for a model

public *string* **getModelSource** (*unknown* \$model)

Returns the mapped source for a model

public **setModelSchema** (*unknown* \$model, *unknown* \$schema)

Sets the mapped schema for a model

public *string* **getModelSchema** (*unknown* \$model)

Returns the mapped schema for a model

public **setConnectionService** (*unknown* \$model, *unknown* \$connectionService)

Sets both write and read connection service for a model

public **setWriteConnectionService** (*unknown* \$model, *unknown* \$connectionService)

Sets write connection service for a model

public **setReadConnectionService** (*unknown* \$model, *unknown* \$connectionService)

Sets read connection service for a model

public [Phalcon\Db\AdapterInterface](#) **getReadConnection** (*unknown* \$model)

Returns the connection to read data related to a model

public [Phalcon\Db\AdapterInterface](#) **getWriteConnection** (*unknown \$model*)

Returns the connection to write data related to a model

public **getReadConnectionService** (*unknown \$model*)

Returns the connection service name used to read data related to a model

public **getWriteConnectionService** (*unknown \$model*)

Returns the connection service name used to write data related to a model

public **notifyEvent** (*unknown \$eventName, unknown \$model*)

Receives events generated in the models and dispatches them to a events-manager if available Notify the behaviors that are listening in the model

public *boolean missingMethod* (*unknown \$model, unknown \$eventName, unknown \$data*)

Dispatch a event to the listeners and behaviors This method expects that the endpoint listeners/behaviors returns true meaning that a least one was implemented

public **addBehavior** (*unknown \$model, unknown \$behavior*)

Binds a behavior to a model

public **keepSnapshots** (*unknown \$model, unknown \$keepSnapshots*)

Sets if a model must keep snapshots

public *boolean isKeepingSnapshots* (*unknown \$model*)

Checks if a model is keeping snapshots for the queried records

public **useDynamicUpdate** (*unknown \$model, unknown \$dynamicUpdate*)

Sets if a model must use dynamic update instead of the all-field update

public *boolean isUsingDynamicUpdate* (*unknown \$model*)

Checks if a model is using dynamic update instead of all-field update

public [Phalcon\Mvc\Model\Relation](#) **addHasOne** (*unknown \$model, unknown \$fields, unknown \$referencedModel, unknown \$referencedFields, [unknown \$options]*)

Setup a 1-1 relation between two models

public [Phalcon\Mvc\Model\Relation](#) **addBelongsTo** (*unknown \$model, unknown \$fields, unknown \$referencedModel, unknown \$referencedFields, [unknown \$options]*)

Setup a relation reverse many to one between two models

public **addHasMany** (*unknown \$model, unknown \$fields, unknown \$referencedModel, unknown \$referencedFields, [unknown \$options]*)

Setup a relation 1-n between two models

public [Phalcon\Mvc\Model\Relation](#) **addHasManyToMany** (*unknown \$model, unknown \$fields, unknown \$intermediateModel, unknown \$intermediateFields, unknown \$intermediateReferencedFields, unknown \$referencedModel, unknown \$referencedFields, [unknown \$options]*)

Setups a relation n-m between two models

public *boolean existsBelongsTo* (*unknown \$modelName, unknown \$modelRelation*)

Checks whether a model has a belongsTo relation with another model

public boolean existsHasMany (*unknown \$modelName, unknown \$modelRelation*)

Checks whether a model has ahasMany relation with another model

public boolean existsHasOne (*unknown \$modelName, unknown \$modelRelation*)

Checks whether a model has ahasOne relation with another model

public boolean existsHasManyToMany (*unknown \$modelName, unknown \$modelRelation*)

Checks whether a model has ahasManyToMany relation with another model

public Phalcon\Mvc\Model\Relation|false getRelationByAlias (*unknown \$modelName, unknown \$alias*)

Returns a relation by its alias

public Phalcon\Mvc\Model\Resultset\Simple|Phalcon\Mvc\Model\Resultset\Simple|false getRelationRecords (*unknown \$relation, unknown \$method, unknown \$record, [unknown \$parameters]*)

Helper method to query records based on a relation definition

public object getReusableRecords (*unknown \$modelName, unknown \$key*)

Returns a reusable object from the internal list

public setReusableRecords (*unknown \$modelName, unknown \$key, unknown \$records*)

Stores a reusable record in the internal list

public clearReusableObjects()

Clears the internal reusable list

public Phalcon\Mvc\Model\ResultsetInterface getBelongsToRecords (*unknown \$method, unknown \$modelName, unknown \$modelRelation, unknown \$record, [unknown \$parameters]*)

Gets belongsTo related records from a model

public Phalcon\Mvc\Model\ResultsetInterface getHasManyRecords (*unknown \$method, unknown \$modelName, unknown \$modelRelation, unknown \$record, [unknown \$parameters]*)

GetshasMany related records from a model

public Phalcon\Mvc\ModelInterface getHasOneRecords (*unknown \$method, unknown \$modelName, unknown \$modelRelation, unknown \$record, [unknown \$parameters]*)

Gets belongsTo related records from a model

public Phalcon\Mvc\Model\RelationInterface[] getBelongsTo (*unknown \$model*)

Gets all the belongsTo relations defined in a model

```
<?php
```

```
$relations = $modelsManager->getBelongsTo(new Robots());
```

public Phalcon\Mvc\Model\RelationInterface[] getHasMany (*unknown \$model*)

GetshasMany relations defined on a model

public array getHasOne (*Phalcon\Mvc\ModelInterface \$model*)

GetshasOne relations defined on a model

public Phalcon\Mvc\Model\RelationInterface[] getHasManyToMany (*unknown \$model*)

GetshasManyToMany relations defined on a model

public array getHasOneAndHasMany (*unknown \$model*)

Gets hasOne relations defined on a model

```
public Phalcon\Mvc\Model\RelationInterface [] getRelations (string $modelName)
```

Query all the relationships defined on a model

```
public Phalcon\Mvc\Model\RelationInterface [] getRelationsBetween (unknown $first, unknown $second)
```

Query the first relationship defined between two models

```
public Phalcon\Mvc\Model\QueryInterface createQuery (unknown $phql)
```

Creates a Phalcon\Mvc\Model\Query without execute it

```
public Phalcon\Mvc\Model\QueryInterface executeQuery (unknown $phql, [unknown $placeholders], [unknown $types])
```

Creates a Phalcon\Mvc\Model\Query and execute it

```
public Phalcon\Mvc\Model\Query\BuilderInterface createBuilder ([unknown $params])
```

Creates a Phalcon\Mvc\Model\Query\Builder

```
public Phalcon\Mvc\Model\QueryInterface getLastQuery ()
```

Returns the lastest query created or executed in the models manager

```
public registerNamespaceAlias (unknown $alias, unknown $namespaceName)
```

Registers shorter aliases for namespaces in PHQL statements

```
public string getNamespaceAlias (unknown $alias)
```

Returns a real namespace from its alias

```
public array getNamespaceAliases ()
```

Returns all the registered namespace aliases

2.58.156 Class Phalcon\Mvc\Model\Message

implements Phalcon\Mvc\Model\MessageInterface

Encapsulates validation info generated before save/delete records fails

```
<?php

use Phalcon\Mvc\Model\Message as Message;

class Robots extends \Phalcon\Mvc\Model
{

    public function beforeSave()
    {
        if ($this->name == 'Peter') {
            text = "A robot cannot be named Peter";
            field = "name";
            type = "InvalidValue";
            message = new Message(text, field, type);
            $this->appendMessage(message);
        }
    }
}
```

Methods

```
public __construct (unknown $message, [unknown $field], [unknown $type], [unknown $model])
Phalcon\Mvc\Model\Message constructor

public Phalcon\Mvc\Model\MessageInterface setType (unknown $type)
Sets message type

public string getType ()
Returns message type

public Phalcon\Mvc\Model\MessageInterface setMessage (unknown $message)
Sets verbose message

public string getMessage ()
Returns verbose message

public Phalcon\Mvc\Model\MessageInterface setField (unknown $field)
Sets field name related to message

public string getField ()
Returns field name related to message

public Phalcon\Mvc\Model\Message setModel (unknown $model)
Set the model who generates the message

public Phalcon\Mvc\ModelInterface getModel ()
Returns the model that produced the message

public string __toString ()
Magic __toString method returns verbose message

public static Phalcon\Mvc\Model\MessageInterface __set_state (unknown $message)
Magic __set_state helps to re-build messages variable exporting
```

2.58.157 Abstract class Phalcon\Mvc\Model\MetaData

implements Phalcon\Di\InjectionAwareInterface

Because Phalcon\Mvc\Model requires meta-data like field names, data types, primary keys, etc. this component collect them and store for further querying by Phalcon\Mvc\Model. Phalcon\Mvc\Model\MetaData can also use adapters to store temporarily or permanently the meta-data. A standard Phalcon\Mvc\Model\MetaData can be used to query model attributes:

```
<?php

$metaData = new \Phalcon\Mvc\Model\MetaData\Memory();
$attributes = $metaData->getAttributes(new Robots());
print_r($attributes);
```

Constants

integer **MODELS_ATTRIBUTES**
integer **MODELS_PRIMARY_KEY**
integer **MODELS_NON_PRIMARY_KEY**
integer **MODELS_NOT_NULL**
integer **MODELS_DATA_TYPES**
integer **MODELS_DATA_TYPES_NUMERIC**
integer **MODELS_DATE_AT**
integer **MODELS_DATE_IN**
integer **MODELS_IDENTITY_COLUMN**
integer **MODELS_DATA_TYPES_BIND**
integer **MODELS_AUTOMATIC_DEFAULT_INSERT**
integer **MODELS_AUTOMATIC_DEFAULT_UPDATE**
integer **MODELS_DEFAULT_VALUES**
integer **MODELS_COLUMN_MAP**
integer **MODELS_REVERSE_COLUMN_MAP**

Methods

final protected **_initialize** (*unknown* \$model, *unknown* \$key, *unknown* \$table, *unknown* \$schema)

Initialize the metadata for certain table

public **setDI** (*unknown* \$dependencyInjector)

Sets the DependencyInjector container

public **Phalcon\DiInterface getDI** ()

Returns the DependencyInjector container

public **setStrategy** (*unknown* \$strategy)

Set the meta-data extraction strategy

public **Phalcon\Mvc\Model\MetaData\StrategyInterface getStrategy** ()

Return the strategy to obtain the meta-data

final public *array* **readMetaData** (*unknown* \$model)

Reads the complete meta-data for certain model

```
<?php  
print_r($metaData->readMetaData(new Robots()));
```

final public *mixed* **readMetaDataIndex** (*unknown* \$model, *unknown* \$index)

Reads meta-data for certain model using a MODEL_* constant

```
<?php
```

```
print_r($metaData->writeColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP), array('leNa'));
```

final public **writeMetaDataIndex** (*unknown* \$model, *unknown* \$index, *unknown* \$data)

Writes meta-data for certain model using a MODEL_* constant

```
<?php
```

```
print_r($metaData->writeColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP), array('leNa'));
```

final public *array* **readColumnMap** (*unknown* \$model)

Reads the ordered/reversed column map for certain model

```
<?php
```

```
print_r($metaData->readColumnMap(new Robots()));
```

final public **readColumnMapIndex** (*unknown* \$model, *unknown* \$index)

Reads column-map information for certain model using a MODEL_* constant

```
<?php
```

```
print_r($metaData->readColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP));
```

public *array* **getAttributes** (*Phalcon\Mvc\ModelInterface* \$model)

Returns table attributes names (fields)

```
<?php
```

```
print_r($metaData->getAttributes(new Robots()));
```

public *array* **getPrimaryKeyAttributes** (*unknown* \$model)

Returns an array of fields which are part of the primary key

```
<?php
```

```
print_r($metaData->getPrimaryKeyAttributes(new Robots()));
```

public *array* **getNonPrimaryKeyAttributes** (*unknown* \$model)

Returns an array of fields which are not part of the primary key

```
<?php
```

```
print_r($metaData->getNonPrimaryKeyAttributes(new Robots()));
```

public *array* **getNotNullAttributes** (*unknown* \$model)

Returns an array of not null attributes

```
<?php
```

```
print_r($metaData->getNotNullAttributes(new Robots()));
```

public *array* **getDataTypes** (*unknown* \$model)

Returns attributes and their data types

```
<?php  
print_r($metaData->getDataTypes(new Robots()));
```

public array getDataTypesNumeric (unknown \$model)

Returns attributes which types are numerical

```
<?php  
print_r($metaData->getDataTypesNumeric(new Robots()));
```

public string getIdentityField (unknown \$model)

Returns the name of identity field (if one is present)

```
<?php  
print_r($metaData->getIdentityField(new Robots()));
```

public array getBindTypes (unknown \$model)

Returns attributes and their bind data types

```
<?php  
print_r($metaData->getBindTypes(new Robots()));
```

public array getAutomaticCreateAttributes (unknown \$model)

Returns attributes that must be ignored from the INSERT SQL generation

```
<?php  
print_r($metaData->getAutomaticCreateAttributes(new Robots()));
```

public array getAutomaticUpdateAttributes (unknown \$model)

Returns attributes that must be ignored from the UPDATE SQL generation

```
<?php  
print_r($metaData->getAutomaticUpdateAttributes(new Robots()));
```

public setAutomaticCreateAttributes (unknown \$model, unknown \$attributes)

Set the attributes that must be ignored from the INSERT SQL generation

```
<?php  
$metaData->setAutomaticCreateAttributes(new Robots(), array('created_at' => true));
```

public setAutomaticUpdateAttributes (unknown \$model, unknown \$attributes)

Set the attributes that must be ignored from the UPDATE SQL generation

```
<?php  
$metaData->setAutomaticUpdateAttributes(new Robots(), array('modified_at' => true));
```

public array getDefaultValues (unknown \$model)

Returns attributes (which have default values) and their default values

```
<?php
print_r($metaData->getDefaultValue($model));
```

public array getColumnMap (unknown \$model)

Returns the column map if any

```
<?php
print_r($metaData->getColumnMap($model));
```

public array getReverseColumnMap (unknown \$model)

Returns the reverse column map if any

```
<?php
print_r($metaData->getReverseColumnMap($model));
```

public boolean hasAttribute (unknown \$model, unknown \$attribute)

Check if a model has certain attribute

```
<?php
var_dump($metaData->hasAttribute($model, 'name'));
```

public boolean isEmpty ()

Checks if the internal meta-data container is empty

```
<?php
var_dump($metaData->isEmpty());
```

public void reset ()

Resets internal meta-data in order to regenerate it

```
<?php
$metaData->reset();
```

2.58.158 Class Phalcon\Mvc\Model\MetaData\Apc

extends abstract class **Phalcon\Mvc\Model\MetaData**

implements **Phalcon\Di\InjectionAwareInterface, Phalcon\Mvc\Model\MetaDataInterface**

Stores model meta-data in the APC cache. Data will be erased if the web server is restarted. By default meta-data is stored for 48 hours (172800 seconds). You can query the meta-data by printing `apc_fetch('PMM')` or `apc_fetch('PMMmy-app-id')`

```
<?php
$metaData = new \Phalcon\Mvc\Model\MetaData\Apc([
    'prefix' => 'my-app-id',
    'lifetime' => 86400
]);
```

Constants

integer **MODELS_ATTRIBUTES**
integer **MODELS_PRIMARY_KEY**
integer **MODELS_NON_PRIMARY_KEY**
integer **MODELS_NOT_NULL**
integer **MODELS_DATA_TYPES**
integer **MODELS_DATA_TYPES_NUMERIC**
integer **MODELS_DATE_AT**
integer **MODELS_DATE_IN**
integer **MODELS_IDENTITY_COLUMN**
integer **MODELS_DATA_TYPES_BIND**
integer **MODELS_AUTOMATIC_DEFAULT_INSERT**
integer **MODELS_AUTOMATIC_DEFAULT_UPDATE**
integer **MODELS_DEFAULT_VALUES**
integer **MODELS_COLUMN_MAP**
integer **MODELS_REVERSE_COLUMN_MAP**

Methods

public __construct ([*unknown* \$options])
Phalcon\Mvc\Model\MetaData\Apc constructor

public array read (*unknown* \$key)
Reads meta-data from APC

public write (*unknown* \$key, *unknown* \$data)
Writes the meta-data to APC

final protected _initialize (*unknown* \$model, *unknown* \$key, *unknown* \$table, *unknown* \$schema) inherited from Phalcon\Mvc\Model\MetaData
Initialize the metadata for certain table

public setDI (*unknown* \$dependencyInjector) inherited from Phalcon\Mvc\Model\MetaData
Sets the DependencyInjector container

public Phalcon\DiInterface getDI () inherited from Phalcon\Mvc\Model\MetaData
Returns the DependencyInjector container

public setStrategy (*unknown* \$strategy) inherited from Phalcon\Mvc\Model\MetaData
Set the meta-data extraction strategy

public Phalcon\Mvc\Model\MetaData\StrategyInterface getStrategy () inherited from Phalcon\Mvc\Model\MetaData
Return the strategy to obtain the meta-data

final public array readMetaData (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData
Reads the meta-data from the specified model

Reads the complete meta-data for certain model

```
<?php
print_r($metaData->readMetaData(new Robots()));
```

final public *mixed* **readMetaDataIndex** (*unknown* \$model, *unknown* \$index) inherited from Phalcon\Mvc\Model\MetaData

Reads meta-data for certain model using a MODEL_* constant

```
<?php
print_r($metaData->writeColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP), array('leN'));
```

final public **writeMetaDataIndex** (*unknown* \$model, *unknown* \$index, *unknown* \$data) inherited from Phalcon\Mvc\Model\MetaData

Writes meta-data for certain model using a MODEL_* constant

```
<?php
print_r($metaData->writeColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP), array('leN'));
```

final public *array* **readColumnMap** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Reads the ordered/reversed column map for certain model

```
<?php
print_r($metaData->readColumnMap(new Robots()));
```

final public **readColumnMapIndex** (*unknown* \$model, *unknown* \$index) inherited from Phalcon\Mvc\Model\MetaData

Reads column-map information for certain model using a MODEL_* constant

```
<?php
print_r($metaData->readColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP));
```

public *array* **getAttributes** (Phalcon\Mvc\ModelInterface \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns table attributes names (fields)

```
<?php
print_r($metaData->getAttributes(new Robots()));
```

public *array* **getPrimaryKeyAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of fields which are part of the primary key

```
<?php
print_r($metaData->getPrimaryKeyAttributes(new Robots()));
```

public *array* **getNonPrimaryKeyAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of fields which are not part of the primary key

```
<?php  
print_r($metaData->getNonPrimaryKeyAttributes(new Robots()));
```

public **array** **getNotNullAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of not null attributes

```
<?php  
print_r($metaData->getNotNullAttributes(new Robots()));
```

public **array** **getDataTypes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes and their data types

```
<?php  
print_r($metaData->getDataTypes(new Robots()));
```

public **array** **getDataTypesNumeric** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes which types are numerical

```
<?php  
print_r($metaData->getDataTypesNumeric(new Robots()));
```

public **string** **getIdentityField** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns the name of identity field (if one is present)

```
<?php  
print_r($metaData->getIdentityField(new Robots()));
```

public **array** **getBindTypes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes and their bind data types

```
<?php  
print_r($metaData->getBindTypes(new Robots()));
```

public **array** **getAutomaticCreateAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes that must be ignored from the INSERT SQL generation

```
<?php  
print_r($metaData->getAutomaticCreateAttributes(new Robots()));
```

public **array** **getAutomaticUpdateAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes that must be ignored from the UPDATE SQL generation

```
<?php  
print_r($metaData->getAutomaticUpdateAttributes(new Robots()));
```

public **setAutomaticCreateAttributes** (*unknown* \$model, *unknown* \$attributes) inherited from Phalcon\Mvc\Model\MetaData

Set the attributes that must be ignored from the INSERT SQL generation

```
<?php
$metaData->setAutomaticCreateAttributes(new Robots(), array('created_at' => true));
```

public **setAutomaticUpdateAttributes** (*unknown* \$model, *unknown* \$attributes) inherited from Phalcon\Mvc\Model\MetaData

Set the attributes that must be ignored from the UPDATE SQL generation

```
<?php
$metaData->setAutomaticUpdateAttributes(new Robots(), array('modified_at' => true));
```

public **array getDefaultValues** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes (which have default values) and their default values

```
<?php
print_r($metaData->getDefaultValues(new Robots()));
```

public **array getColumnMap** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns the column map if any

```
<?php
print_r($metaData->getColumnMap(new Robots()));
```

public **array getReverseColumnMap** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns the reverse column map if any

```
<?php
print_r($metaData->getReverseColumnMap(new Robots()));
```

public **boolean hasAttribute** (*unknown* \$model, *unknown* \$attribute) inherited from Phalcon\Mvc\Model\MetaData

Check if a model has certain attribute

```
<?php
var_dump($metaData->hasAttribute(new Robots(), 'name'));
```

public **boolean isEmpty** () inherited from Phalcon\Mvc\Model\MetaData

Checks if the internal meta-data container is empty

```
<?php
var_dump($metaData->isEmpty());
```

public **reset** () inherited from Phalcon\Mvc\Model\MetaData

Resets internal meta-data in order to regenerate it

```
<?php
$metaData->reset();
```

2.58.159 Class Phalcon\\Mvc\\Model\\MetaData\\Files

extends abstract class [Phalcon\\Mvc\\Model\\MetaData](#)

implements [Phalcon\\Di\\InjectionAwareInterface](#), [Phalcon\\Mvc\\Model\\MetaDataInterface](#)

Stores model meta-data in PHP files.

```
<?php

$metaData = new \Phalcon\Mvc\Model\MetaData\Files(array(
    'metaDataDir' => 'app/cache/metadata/'
));
```

Constants

$metaData->setAutomaticUpdateAttributes(new Robots(), array('modified_at' => true));
```

public array getDefaultValues (unknown \$model) inherited from Phalcon\\Mvc\\Model\\MetaData

Returns attributes (which have default values) and their default values

```
<?php
print_r($metaData->getDefaultValues(new Robots()));
```

public array getColumnMap (unknown \$model) inherited from Phalcon\\Mvc\\Model\\MetaData

Returns the column map if any

```
<?php
print_r($metaData->getColumnMap(new Robots()));
```

public array getReverseColumnMap (unknown \$model) inherited from Phalcon\\Mvc\\Model\\MetaData

Returns the reverse column map if any

```
<?php
print_r($metaData->getReverseColumnMap(new Robots()));
```

public boolean hasAttribute (unknown \$model, unknown \$attribute) inherited from Phalcon\\Mvc\\Model\\MetaData

Check if a model has certain attribute

```
<?php
var_dump($metaData->hasAttribute(new Robots(), 'name'));
```

public *boolean* **isEmpty** () inherited from Phalcon\Mvc\Model\MetaData

Checks if the internal meta-data container is empty

```
<?php  
  
var_dump($metaData->isEmpty());
```

public **reset** () inherited from Phalcon\Mvc\Model\MetaData

Resets internal meta-data in order to regenerate it

```
<?php  
  
$metaData->reset();
```

2.58.160 Class Phalcon\Mvc\Model\MetaData\Memory

extends abstract class Phalcon\Mvc\Model\MetaData

implements Phalcon\Di\InjectionAwareInterface, Phalcon\Mvc\Model\MetaDataInterface

Stores model meta-data in memory. Data will be erased when the request finishes

Constants

integer MODELS_ATTRIBUTES

integer MODELS_PRIMARY_KEY

integer MODELS_NON_PRIMARY_KEY

integer MODELS_NOT_NULL

integer MODELS_DATA_TYPES

integer MODELS_DATA_TYPES_NUMERIC

integer MODELS_DATE_AT

integer MODELS_DATE_IN

integer MODELS_IDENTITY_COLUMN

integer MODELS_DATA_TYPES_BIND

integer MODELS_AUTOMATIC_DEFAULT_INSERT

integer MODELS_AUTOMATIC_DEFAULT_UPDATE

integer MODELS_DEFAULT_VALUES

integer MODELS_COLUMN_MAP

integer MODELS_REVERSE_COLUMN_MAP

Methods

public **__construct** ([*unknown* \$options])

Phalcon\Mvc\Model\MetaData\Memory constructor

public *array* **read** (*unknown* \$key)

Reads the meta-data from temporal memory

```
public write (unknown $key, unknown $data)
```

Writes the meta-data to temporal memory

```
final protected _initialize (unknown $model, unknown $key, unknown $stable, unknown $schema) inherited from Phalcon\Mvc\Model\MetaData
```

Initialize the metadata for certain table

```
public setDI (unknown $dependencyInjector) inherited from Phalcon\Mvc\Model\MetaData
```

Sets the DependencyInjector container

```
public Phalcon\DiInterface getDI () inherited from Phalcon\Mvc\Model\MetaData
```

Returns the DependencyInjector container

```
public setStrategy (unknown $strategy) inherited from Phalcon\Mvc\Model\MetaData
```

Set the meta-data extraction strategy

```
public Phalcon\Mvc\Model\MetaData\StrategyInterface getStrategy () inherited from Phalcon\Mvc\Model\MetaData
```

Return the strategy to obtain the meta-data

```
final public array readMetaData (unknown $model) inherited from Phalcon\Mvc\Model\MetaData
```

Reads the complete meta-data for certain model

```
<?php  
print_r ($metaData->readMetaData (new Robots ()) );
```

```
final public mixed readMetaDataIndex (unknown $model, unknown $index) inherited from Phalcon\Mvc\Model\MetaData
```

Reads meta-data for certain model using a MODEL_* constant

```
<?php
```

```
print_r ($metaData->writeColumnMapIndex (new Robots (), MetaData::MODELS_REVERSE_COLUMN_MAP, array ('leNa
```

```
final public writeMetaDataIndex (unknown $model, unknown $index, unknown $data) inherited from Phalcon\Mvc\Model\MetaData
```

Writes meta-data for certain model using a MODEL_* constant

```
<?php
```

```
print_r ($metaData->writeColumnMapIndex (new Robots (), MetaData::MODELS_REVERSE_COLUMN_MAP, array ('leNa
```

```
final public array readColumnMap (unknown $model) inherited from Phalcon\Mvc\Model\MetaData
```

Reads the ordered/reversed column map for certain model

```
<?php
```

```
print_r ($metaData->readColumnMap (new Robots ()) );
```

```
final public readColumnMapIndex (unknown $model, unknown $index) inherited from Phalcon\Mvc\Model\MetaData
```

Reads column-map information for certain model using a MODEL_* constant

```
<?php  
print_r($metaData->readColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP));
```

public array **getAttributes** (Phalcon\Mvc\ModelInterface \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns table attributes names (fields)

```
<?php  
print_r($metaData->getAttributes(new Robots()));
```

public array **getPrimaryKeyAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of fields which are part of the primary key

```
<?php  
print_r($metaData->getPrimaryKeyAttributes(new Robots()));
```

public array **getNonPrimaryKeyAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of fields which are not part of the primary key

```
<?php  
print_r($metaData->getNonPrimaryKeyAttributes(new Robots()));
```

public array **getNotNullAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of not null attributes

```
<?php  
print_r($metaData->getNotNullAttributes(new Robots()));
```

public array **getDataTypes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes and their data types

```
<?php  
print_r($metaData->getDataTypes(new Robots()));
```

public array **getDataTypesNumeric** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes which types are numerical

```
<?php  
print_r($metaData->getDataTypesNumeric(new Robots()));
```

public string **getIdentityField** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns the name of identity field (if one is present)

```
<?php  
print_r($metaData->getIdentityField(new Robots()));
```

public array **getBindTypes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes and their bind data types

```
<?php
print_r($metaData->getBindTypes(new Robots()));
```

public **array getAutomaticCreateAttributes** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes that must be ignored from the INSERT SQL generation

```
<?php
print_r($metaData->getAutomaticCreateAttributes(new Robots()));
```

public **array getAutomaticUpdateAttributes** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes that must be ignored from the UPDATE SQL generation

```
<?php
print_r($metaData->getAutomaticUpdateAttributes(new Robots()));
```

public **setAutomaticCreateAttributes** (*unknown \$model, unknown \$attributes*) inherited from Phalcon\Mvc\Model\MetaData

Set the attributes that must be ignored from the INSERT SQL generation

```
<?php
$metaData->setAutomaticCreateAttributes(new Robots(), array('created_at' => true));
```

public **setAutomaticUpdateAttributes** (*unknown \$model, unknown \$attributes*) inherited from Phalcon\Mvc\Model\MetaData

Set the attributes that must be ignored from the UPDATE SQL generation

```
<?php
$metaData->setAutomaticUpdateAttributes(new Robots(), array('modified_at' => true));
```

public **array getDefaultValues** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes (which have default values) and their default values

```
<?php
print_r($metaData->getDefaultValues(new Robots()));
```

public **array getColumnMap** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns the column map if any

```
<?php
print_r($metaData->getColumnMap(new Robots()));
```

public **array getReverseColumnMap** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns the reverse column map if any

```
<?php
print_r($metaData->getReverseColumnMap(new Robots()));
```

public *boolean* **hasAttribute** (*unknown* \$model, *unknown* \$attribute) inherited from Phalcon\Mvc\Model\MetaData

Check if a model has certain attribute

```
<?php  
  
var_dump ($metaData->hasAttribute (new Robots (), 'name'));
```

public *boolean* **isEmpty** () inherited from Phalcon\Mvc\Model\MetaData

Checks if the internal meta-data container is empty

```
<?php  
  
var_dump ($metaData->isEmpty ());
```

public **reset** () inherited from Phalcon\Mvc\Model\MetaData

Resets internal meta-data in order to regenerate it

```
<?php  
  
$metaData->reset ();
```

2.58.161 Class Phalcon\Mvc\Model\MetaData\Session

extends abstract class Phalcon\Mvc\Model\MetaData

implements Phalcon\Di\InjectionAwareInterface, Phalcon\Mvc\Model\MetaDataInterface

Stores model meta-data in session. Data will be erased when the session finishes. Meta-data are permanent while the session is active. You can query the meta-data by printing `$_SESSION['$PMM$']`

```
<?php  
  
$metaData = new \Phalcon\Mvc\Model\Metadata\Session (array (  
    'prefix' => 'my-app-id'  
) );
```

Constants

integer MODELS_ATTRIBUTES

integer MODELS_NOT_NULL

integer MODELS_DATA_TYPES

integer MODELS_DATA_TYPES_NUMERIC

integer MODELS_DATE_AT

integer MODELS_DATE_IN

integer MODELS_IDENTITY_COLUMN

integer MODELS_DATA_TYPES_BIND

integer MODELS_AUTOMATIC_DEFAULT_INSERT

integer **MODELS_AUTOMATIC_DEFAULT_UPDATE**
integer **MODELS_DEFAULT_VALUES**
integer **MODELS_COLUMN_MAP**
integer **MODELS_REVERSE_COLUMN_MAP**

Methods

public __construct ([*unknown* \$options])
 Phalcon\Mvc\Model\MetaData\Session constructor
public array read (*unknown* \$key)
 Reads meta-data from \$_SESSION
public write (*unknown* \$key, *unknown* \$data)
 Writes the meta-data to \$_SESSION
final protected _initialize (*unknown* \$model, *unknown* \$key, *unknown* \$table, *unknown* \$schema) inherited from Phalcon\Mvc\Model\MetaData
 Initialize the metadata for certain table
public setDI (*unknown* \$dependencyInjector) inherited from Phalcon\Mvc\Model\MetaData
 Sets the DependencyInjector container
public Phalcon\DiInterface getDI () inherited from Phalcon\Mvc\Model\MetaData
 Returns the DependencyInjector container
public setStrategy (*unknown* \$strategy) inherited from Phalcon\Mvc\Model\MetaData
 Set the meta-data extraction strategy
public Phalcon\Mvc\Model\MetaData\StrategyInterface getStrategy () inherited from Phalcon\Mvc\Model\MetaData
 Return the strategy to obtain the meta-data
final public array readMetaData (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData
 Reads the complete meta-data for certain model

```
<?php
print_r($metaData->readMetaData(new Robots()));
```

final public mixed readMetaDataIndex (*unknown* \$model, *unknown* \$index) inherited from Phalcon\Mvc\Model\MetaData

Reads meta-data for certain model using a MODEL_* constant

```
<?php
print_r($metaData->writeColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP, array('leNa
```

final public writeMetaDataIndex (*unknown* \$model, *unknown* \$index, *unknown* \$data) inherited from Phalcon\Mvc\Model\MetaData

Writes meta-data for certain model using a MODEL_* constant

```
<?php  
print_r($metaData->writeColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP), array('leNa
```

final public *array* **readColumnMap** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Reads the ordered/reversed column map for certain model

```
<?php  
print_r($metaData->readColumnMap(new Robots()));
```

final public **readColumnMapIndex** (*unknown* \$model, *unknown* \$index) inherited from Phalcon\Mvc\Model\MetaData

Reads column-map information for certain model using a MODEL_* constant

```
<?php  
print_r($metaData->readColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP));
```

public *array* **getAttributes** (Phalcon\Mvc\ModelInterface \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns table attributes names (fields)

```
<?php  
print_r($metaData->getAttributes(new Robots()));
```

public *array* **getPrimaryKeyAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of fields which are part of the primary key

```
<?php  
print_r($metaData->getPrimaryKeyAttributes(new Robots()));
```

public *array* **getNonPrimaryKeyAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of fields which are not part of the primary key

```
<?php  
print_r($metaData->getNonPrimaryKeyAttributes(new Robots()));
```

public *array* **getNotNullAttributes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of not null attributes

```
<?php  
print_r($metaData->getNotNullAttributes(new Robots()));
```

public *array* **getDataTypes** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes and their data types

```
<?php  
print_r($metaData->getDataTypes(new Robots()));
```

public *array* **getDataTypesNumeric** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes which types are numerical

```
<?php
print_r($metaData->getDataTypesNumeric(new Robots()));
```

public string getIdentityField (unknown \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns the name of identity field (if one is present)

```
<?php
print_r($metaData->getIdentityField(new Robots()));
```

public array getBindTypes (unknown \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes and their bind data types

```
<?php
print_r($metaData->getBindTypes(new Robots()));
```

public array getAutomaticCreateAttributes (unknown \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes that must be ignored from the INSERT SQL generation

```
<?php
print_r($metaData->getAutomaticCreateAttributes(new Robots()));
```

public array getAutomaticUpdateAttributes (unknown \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes that must be ignored from the UPDATE SQL generation

```
<?php
print_r($metaData->getAutomaticUpdateAttributes(new Robots()));
```

public setAutomaticCreateAttributes (unknown \$model, unknown \$attributes) inherited from Phalcon\Mvc\Model\MetaData

Set the attributes that must be ignored from the INSERT SQL generation

```
<?php
$metaData->setAutomaticCreateAttributes(new Robots(), array('created_at' => true));
```

public setAutomaticUpdateAttributes (unknown \$model, unknown \$attributes) inherited from Phalcon\Mvc\Model\MetaData

Set the attributes that must be ignored from the UPDATE SQL generation

```
<?php
$metaData->setAutomaticUpdateAttributes(new Robots(), array('modified_at' => true));
```

public array getDefaultValues (unknown \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes (which have default values) and their default values

```
<?php
print_r($metaData->getDefaultValues(new Robots()));
```

public *array* **getColumnMap** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns the column map if any

```
<?php  
print_r($metaData->getColumnMap(new Robots()));
```

public *array* **getReverseColumnMap** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns the reverse column map if any

```
<?php  
print_r($metaData->getReverseColumnMap(new Robots()));
```

public *boolean* **hasAttribute** (*unknown* \$model, *unknown* \$attribute) inherited from Phalcon\Mvc\Model\MetaData

Check if a model has certain attribute

```
<?php  
var_dump($metaData->hasAttribute(new Robots(), 'name'));
```

public *boolean* **isEmpty** () inherited from Phalcon\Mvc\Model\MetaData

Checks if the internal meta-data container is empty

```
<?php  
var_dump($metaData->isEmpty());
```

public **reset** () inherited from Phalcon\Mvc\Model\MetaData

Resets internal meta-data in order to regenerate it

```
<?php  
$metaData->reset();
```

2.58.162 Class Phalcon\Mvc\Model\MetaData\Strategy\Annotations

implements Phalcon\Mvc\Model\MetaData\StrategyInterface

Methods

final public *array* **getMetaData** (*unknown* \$model, *unknown* \$dependencyInjector)

The meta-data is obtained by reading the column descriptions from the database information schema

final public *array* **getColumnMaps** (*unknown* \$model, *unknown* \$dependencyInjector)

Read the model's column map, this can't be inferred

2.58.163 Class Phalcon\Mvc\Model\MetaData\Strategy\Introspection

implements Phalcon\Mvc\Model\MetaData\StrategyInterface

Phalcon\Mvc\Model\MetaData\Strategy\Introspection Queries the table meta-data in order to introspect the model's metadata

Methods

`final public array getMetaData (unknown $model, unknown $dependencyInjector)`

The meta-data is obtained by reading the column descriptions from the database information schema

`final public array getColumnMaps (unknown $model, unknown $dependencyInjector)`

Read the model's column map, this can't be inferred

2.58.164 Class Phalcon\Mvc\Model\MetaData\Xcache

extends abstract class `Phalcon\Mvc\Model\MetaData`

implements `Phalcon\Di\InjectionAwareInterface, Phalcon\Mvc\Model\MetaDataInterface`

Stores model meta-data in the XCache cache. Data will be erased if the web server is restarted. By default meta-data is stored for 48 hours (172800 seconds). You can query the meta-data by printing `xcache_get('PMM$')` or `xcache_get('PMM$my-app-id')`

```
<?php

$metaData = new Phalcon\Mvc\Model\Metadata\Xcache(array(
    'prefix' => 'my-app-id',
    'lifetime' => 86400
));
```

Constants

`integer MODELS_ATTRIBUTES`

`integer MODELS_PRIMARY_KEY`

`integer MODELS_NON_PRIMARY_KEY`

`integer MODELS_NOT_NULL`

`integer MODELS_DATA_TYPES`

`integer MODELS_DATA_TYPES_NUMERIC`

`integer MODELS_DATE_AT`

`integer MODELS_DATE_IN`

`integer MODELS_IDENTITY_COLUMN`

`integer MODELS_DATA_TYPES_BIND`

`integer MODELS_AUTOMATIC_DEFAULT_INSERT`

`integer MODELS_AUTOMATIC_DEFAULT_UPDATE`

`integer MODELS_DEFAULT_VALUES`

`integer MODELS_COLUMN_MAP`

`integer MODELS_REVERSE_COLUMN_MAP`

Methods

public **__construct** ([*unknown* \$options])

Phalcon\Mvc\Model\MetaData\Xcache constructor

public **array read** (*unknown* \$key)

Reads metadata from XCache

public **write** (*unknown* \$key, *unknown* \$data)

Writes the metadata to XCache

final protected **_initialize** (*unknown* \$model, *unknown* \$key, *unknown* \$table, *unknown* \$schema) inherited from Phalcon\Mvc\Model\MetaData

Initialize the metadata for certain table

public **setDI** (*unknown* \$dependencyInjector) inherited from Phalcon\Mvc\Model\MetaData

Sets the DependencyInjector container

public **Phalcon\DiInterface getDI** () inherited from Phalcon\Mvc\Model\MetaData

Returns the DependencyInjector container

public **setStrategy** (*unknown* \$strategy) inherited from Phalcon\Mvc\Model\MetaData

Set the meta-data extraction strategy

public **Phalcon\Mvc\Model\MetaData\StrategyInterface getStrategy** () inherited from Phalcon\Mvc\Model\MetaData

Return the strategy to obtain the meta-data

final public **array readMetaData** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Reads the complete meta-data for certain model

```
<?php
```

```
print_r($metaData->readMetaData(new Robots()));
```

final public **mixed readMetaDataIndex** (*unknown* \$model, *unknown* \$index) inherited from Phalcon\Mvc\Model\MetaData

Reads meta-data for certain model using a MODEL_* constant

```
<?php
```

```
print_r($metaData->writeColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP, array('leNa
```

final public **writeMetaDataIndex** (*unknown* \$model, *unknown* \$index, *unknown* \$data) inherited from Phalcon\Mvc\Model\MetaData

Writes meta-data for certain model using a MODEL_* constant

```
<?php
```

```
print_r($metaData->writeColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP, array('leNa
```

final public **array readColumnMap** (*unknown* \$model) inherited from Phalcon\Mvc\Model\MetaData

Reads the ordered/reversed column map for certain model

```
<?php
print_r($metaData->readColumnMap(new Robots()));
```

final public **readColumnMapIndex** (*unknown \$model, unknown \$index*) inherited from Phalcon\Mvc\Model\MetaData

Reads column-map information for certain model using a MODEL_* constant

```
<?php
print_r($metaData->readColumnMapIndex(new Robots(), MetaData::MODELS_REVERSE_COLUMN_MAP));
```

public **getAttributes** (*Phalcon\Mvc\ModelInterface \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns table attributes names (fields)

```
<?php
print_r($metaData->getAttributes(new Robots()));
```

public **getPrimaryKeyAttributes** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of fields which are part of the primary key

```
<?php
print_r($metaData->getPrimaryKeyAttributes(new Robots()));
```

public **getNonPrimaryKeyAttributes** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of fields which are not part of the primary key

```
<?php
print_r($metaData->getNonPrimaryKeyAttributes(new Robots()));
```

public **getNotNullAttributes** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns an array of not null attributes

```
<?php
print_r($metaData->getNotNullAttributes(new Robots()));
```

public **getDataTypes** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes and their data types

```
<?php
print_r($metaData->getDataTypes(new Robots()));
```

public **getDataTypesNumeric** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes which types are numerical

```
<?php
print_r($metaData->getDataTypesNumeric(new Robots()));
```

public **getIdentityField** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns the name of identity field (if one is present)

```
<?php  
print_r($metaData->getIdentityField(new Robots()));
```

public **array getBindTypes** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes and their bind data types

```
<?php  
print_r($metaData->getBindTypes(new Robots()));
```

public **array getAutomaticCreateAttributes** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes that must be ignored from the INSERT SQL generation

```
<?php  
print_r($metaData->getAutomaticCreateAttributes(new Robots()));
```

public **array getAutomaticUpdateAttributes** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes that must be ignored from the UPDATE SQL generation

```
<?php  
print_r($metaData->getAutomaticUpdateAttributes(new Robots()));
```

public **setAutomaticCreateAttributes** (*unknown \$model, unknown \$attributes*) inherited from Phalcon\Mvc\Model\MetaData

Set the attributes that must be ignored from the INSERT SQL generation

```
<?php  
$metaData->setAutomaticCreateAttributes(new Robots(), array('created_at' => true));
```

public **setAutomaticUpdateAttributes** (*unknown \$model, unknown \$attributes*) inherited from Phalcon\Mvc\Model\MetaData

Set the attributes that must be ignored from the UPDATE SQL generation

```
<?php  
$metaData->setAutomaticUpdateAttributes(new Robots(), array('modified_at' => true));
```

public **array getDefaultValues** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns attributes (which have default values) and their default values

```
<?php  
print_r($metaData->getDefaultValues(new Robots()));
```

public **array getColumnMap** (*unknown \$model*) inherited from Phalcon\Mvc\Model\MetaData

Returns the column map if any

```
<?php  
print_r($metaData->getColumnMap(new Robots()));
```

public array getReverseColumnMap (unknown \$model) inherited from Phalcon\Mvc\Model\MetaData

Returns the reverse column map if any

```
<?php
print_r($metaData->getReverseColumnMap(new Robots()));
```

public boolean hasAttribute (unknown \$model, unknown \$attribute) inherited from Phalcon\Mvc\Model\MetaData

Check if a model has certain attribute

```
<?php
var_dump($metaData->hasAttribute(new Robots(), 'name'));
```

public boolean isEmpty () inherited from Phalcon\Mvc\Model\MetaData

Checks if the internal meta-data container is empty

```
<?php
var_dump($metaData->isEmpty());
```

public reset () inherited from Phalcon\Mvc\Model\MetaData

Resets internal meta-data in order to regenerate it

```
<?php
$metaData->reset();
```

2.58.165 Class Phalcon\Mvc\Model\Query

implements Phalcon\Mvc\Model\QueryInterface, Phalcon\Di\InjectionAwareInterface

This class takes a PHQL intermediate representation and executes it.

```
<?php
$phql = "SELECT c.price*0.16 AS taxes, c.* FROM Cars AS c JOIN Brands AS b
        WHERE b.name = :name: ORDER BY c.name";

$result = manager->executeQuery($phql, array(
    "name": "Lamborghini"
));

foreach ($result as $row) {
    echo "Name: ", $row->cars->name, "\n";
    echo "Price: ", $row->cars->price, "\n";
    echo "Taxes: ", $row->taxes, "\n";
}
```

Constants

integer TYPE_SELECT

integer TYPE_INSERT

integer TYPE_UPDATE

integer **TYPE_DELETE**

Methods

public **__construct** ([*unknown* \$phql], [*unknown* \$dependencyInjector])

Phalcon\Mvc\Model\Query constructor

public **setDI** (*unknown* \$dependencyInjector)

Sets the dependency injection container

public **Phalcon\DiInterface** **getDI** ()

Returns the dependency injection container

public **Phalcon\Mvc\Model\Query** **setUniqueRow** (*unknown* \$uniqueRow)

Tells to the query if only the first row in the resultset must be returned

public **boolean** **getUniqueRow** ()

Check if the query is programmed to get only the first row in the resultset

final protected **string** **_getQualified** (*unknown* \$expr)

Replaces the model's name to its source name in a qualified-name expression

final protected **array** **_getCallArgument** (*unknown* \$argument)

Resolves a expression in a single call argument

final protected **array** **_getFunctionCall** (*unknown* \$expr)

Resolves a expression in a single call argument

final protected **string** **_getExpression** (*unknown* \$expr, [*unknown* \$quoting])

Resolves an expression from its intermediate code into a string

final protected **array** **_getSelectColumn** (*unknown* \$column)

Resolves a column from its intermediate representation into an array used to determine if the resulset produced is simple or complex

final protected **string** **_getTable** (*unknown* \$manager, *unknown* \$qualifiedName)

Resolves a table in a SELECT statement checking if the model exists

final protected **array** **_getJoin** (*unknown* \$manager, *unknown* \$join)

Resolves a JOIN clause checking if the associated models exist

final protected **string** **_getJoinType** (*unknown* \$join)

Resolves a JOIN type

final protected **array** **_getSingleJoin** (*unknown* \$joinType, *unknown* \$joinSource, *unknown* \$modelAlias, *unknown* \$joinAlias, *unknown* \$relation)

Resolves joins involving has-one/belongs-to/has-many relations

final protected **array** **_getMultiJoin** (*unknown* \$joinType, *unknown* \$joinSource, *unknown* \$modelAlias, *unknown* \$joinAlias, *unknown* \$relation)

Resolves joins involving many-to-many relations

final protected **array** **_getJoins** (*unknown* \$select)

Processes the JOINs in the query returning an internal representation for the database dialect

final protected array **_getOrderClause** (*array|string* \$order)

Returns a processed order clause for a SELECT statement

final protected array **_getGroupClause** (*array* \$group)

Returns a processed group clause for a SELECT statement

final protected array **_prepareSelect** ()

Analyzes a SELECT intermediate code and produces an array to be executed later

final protected array **_prepareInsert** ()

Analyzes an INSERT intermediate code and produces an array to be executed later

final protected array **_prepareUpdate** ()

Analyzes an UPDATE intermediate code and produces an array to be executed later

final protected array **_prepareDelete** ()

Analyzes a DELETE intermediate code and produces an array to be executed later

public array **parse** ()

Parses the intermediate code produced by Phalcon\Mvc\Model\Query\Lang generating another intermediate representation that could be executed by Phalcon\Mvc\Model\Query

public [Phalcon\Cache\BackendInterface](#) **getCache** ()

Returns the current cache backend instance

final protected [Phalcon\Mvc\Model\ResultsetInterface](#) **_executeSelect** (*unknown* \$intermediate, *unknown* \$bindParams, *unknown* \$bindTypes)

Executes the SELECT intermediate representation producing a Phalcon\Mvc\Model\Resultset

final protected [Phalcon\Mvc\Model\Query>StatusInterface](#) **_executeInsert** (*unknown* \$intermediate, *unknown* \$bindParams, *unknown* \$bindTypes)

Executes the INSERT intermediate representation producing a Phalcon\Mvc\Model\Query>Status

final protected [Phalcon\Mvc\Model\Query>StatusInterface](#) **_executeUpdate** (*unknown* \$intermediate, *unknown* \$bindParams, *unknown* \$bindTypes)

Executes the UPDATE intermediate representation producing a Phalcon\Mvc\Model\Query>Status

final protected [Phalcon\Mvc\Model\Query>StatusInterface](#) **_executeDelete** (*unknown* \$intermediate, *unknown* \$bindParams, *unknown* \$bindTypes)

Executes the DELETE intermediate representation producing a Phalcon\Mvc\Model\Query>Status

final protected [Phalcon\Mvc\Model\ResultsetInterface](#) **_getRelatedRecords** (*unknown* \$model, *unknown* \$intermediate, *unknown* \$bindParams, *unknown* \$bindTypes)

Query the records on which the UPDATE/DELETE operation well be done

public *mixed* **execute** ([*unknown* \$bindParams], [*unknown* \$bindTypes])

Executes a parsed PHQL statement

public [halconMvcModelInterface](#) **getSingleResult** ([*unknown* \$bindParams], [*unknown* \$bindTypes])

Executes the query returning the first result

public [Phalcon\Mvc\Model\Query](#) **setType** (*unknown* \$type)

Sets the type of PHQL statement to be executed

public *int* **getType** ()

Gets the type of PHQL statement executed

public [Phalcon\Mvc\Model\Query](#) **setBindParams** (*unknown* \$bindParams)

Set default bind parameters

public *array* **getBindParams** ()

Returns default bind params

public [Phalcon\Mvc\Model\Query](#) **setBindTypes** (*unknown* \$bindTypes)

Set default bind parameters

public *array* **getBindTypes** ()

Returns default bind types

public [Phalcon\Mvc\Model\Query](#) **setIntermediate** (*unknown* \$intermediate)

Allows to set the IR to be executed

public *array* **getIntermediate** ()

Returns the intermediate representation of the PHQL statement

public [Phalcon\Mvc\Model\Query](#) **cache** (*unknown* \$cacheOptions)

Sets the cache parameters of the query

public **getCacheOptions** ()

Returns the current cache options

2.58.166 Class Phalcon\Mvc\Model\Query\Builder

implements [Phalcon\Mvc\Model\Query\BuilderInterface](#), [Phalcon\Di\InjectionAwareInterface](#)

Helps to create PHQL queries using an OO interface

```
<?php

$params = array(
    'models'      => array('Users'),
    'columns'     => array('id', 'name', 'status'),
    'conditions'  => array(
        array(
            "created > :min: AND created < :max:",
            array("min" => '2013-01-01', 'max' => '2014-01-01'),
            array("min" => PDO::PARAM_STR, 'max' => PDO::PARAM_STR),
        ),
    ),
    // or 'conditions' => "created > '2013-01-01' AND created < '2014-01-01'",
    'group'       => array('id', 'name'),
    'having'      => "name = 'Kamil'",
    'order'        => array('name', 'id'),
    'limit'        => 20,
    'offset'       => 20,
    // or 'limit' => array(20, 20),
```

```
) ;
$queryBuilder = new \Phalcon\Mvc\Model\Query\Builder($params);
```

Methods

public __construct ([*unknown* \$params], [*unknown* \$dependencyInjector])
 Phalcon\\Mvc\\Model\\Query\\Builder constructor
public Phalcon\\Mvc\\Model\\Query\\Builder setDI (*unknown* \$dependencyInjector)
 Sets the DependencyInjector container
public Phalcon\\DiInterface getDI ()
 Returns the DependencyInjector container
public Phalcon\\Mvc\\Model\\Query\\BuilderInterface distinct (*unknown* \$distinct)
 Sets SELECT DISTINCT / SELECT ALL flag
public bool getDistinct ()
 Returns SELECT DISTINCT / SELECT ALL flag
public Phalcon\\Mvc\\Model\\Query\\Builder columns (*unknown* \$columns)
 Sets the columns to be queried

```
<?php
$builder->columns(array('id', 'name'));
```

public stringarray getColumns ()
 Return the columns to be queried
public Phalcon\\Mvc\\Model\\Query\\Builder from (*unknown* \$models)
 Sets the models who makes part of the query

```
<?php
$builder->from('Robots');
$builder->from(array('Robots', 'RobotsParts'));
```

public Phalcon\\Mvc\\Model\\Query\\Builder addFrom (*unknown* \$model, [*unknown* \$alias])
 Add a model to take part of the query

```
<?php
$builder->addFrom('Robots', 'r');
```

public stringarray getFrom ()
 Return the models who makes part of the query
public Phalcon\\Mvc\\Model\\Query\\Builder join (*unknown* \$model, [*unknown* \$conditions], [*unknown* \$alias], [*unknown* \$type])
 Adds a INNER join to the query

```
<?php

$builder->join('Robots');
$builder->join('Robots', 'r.id = RobotsParts.robots_id');
$builder->join('Robots', 'r.id = RobotsParts.robots_id', 'r');
$builder->join('Robots', 'r.id = RobotsParts.robots_id', 'r', 'INNER');
```

public Phalcon\Mvc\Model\Query\Builder **innerJoin** (*unknown* \$model, [*unknown* \$conditions], [*unknown* \$alias])

Adds a INNER join to the query

```
<?php

$builder->innerJoin('Robots');
$builder->innerJoin('Robots', 'r.id = RobotsParts.robots_id');
$builder->innerJoin('Robots', 'r.id = RobotsParts.robots_id', 'r');
```

public Phalcon\Mvc\Model\Query\Builder **leftJoin** (*unknown* \$model, [*unknown* \$conditions], [*unknown* \$alias])

Adds a LEFT join to the query

```
<?php

$builder->leftJoin('Robots', 'r.id = RobotsParts.robots_id', 'r');
```

public Phalcon\Mvc\Model\Query\Builder **rightJoin** (*unknown* \$model, [*unknown* \$conditions], [*unknown* \$alias])

Adds a RIGHT join to the query

```
<?php

$builder->rightJoin('Robots', 'r.id = RobotsParts.robots_id', 'r');
```

public Phalcon\Mvc\Model\Query\Builder **where** (*unknown* \$conditions, [*unknown* \$bindParams], [*unknown* \$bindTypes])

Sets the query conditions

```
<?php

$builder->where(100);
$builder->where('name = "Peter"');
$builder->where('name = :name: AND id > :id:', array('name' => 'Peter', 'id' => 100));
```

public Phalcon\Mvc\Model\Query\Builder **andWhere** (*unknown* \$conditions, [*unknown* \$bindParams], [*unknown* \$bindTypes])

Appends a condition to the current conditions using a AND operator

```
<?php

$builder->andWhere('name = "Peter"');
$builder->andWhere('name = :name: AND id > :id:', array('name' => 'Peter', 'id' => 100));
```

public Phalcon\Mvc\Model\Query\Builder **orWhere** (*unknown* \$conditions, [*unknown* \$bindParams], [*unknown* \$bindTypes])

Appends a condition to the current conditions using a OR operator

```
<?php
```

```
$builder->orWhere('name = "Peter")';
$builder->orWhere('name = :name: AND id > :id:', array('name' => 'Peter', 'id' => 100));
```

public `Phalcon\Mvc\Model\Query\Builder` **betweenWhere** (*unknown \$expr, unknown \$minimum, unknown \$maximum*)

Appends a BETWEEN condition to the current conditions

```
<?php

$builder->betweenWhere('price', 100.25, 200.50);
```

public `Phalcon\Mvc\Model\Query\Builder` **notBetweenWhere** (*unknown \$expr, unknown \$minimum, unknown \$maximum*)

Appends a NOT BETWEEN condition to the current conditions

```
<?php

$builder->notBetweenWhere('price', 100.25, 200.50);
```

public `Phalcon\Mvc\Model\Query\Builder` **inWhere** (*unknown \$expr, unknown \$values*)

Appends an IN condition to the current conditions

```
<?php

$builder->inWhere('id', [1, 2, 3]);
```

public `Phalcon\Mvc\Model\Query\Builder` **notInWhere** (*unknown \$expr, unknown \$values*)

Appends a NOT IN condition to the current conditions

```
<?php

$builder->notInWhere('id', [1, 2, 3]);
```

public `string|array` **getWhere** ()

Return the conditions for the query

public `Phalcon\Mvc\Model\Query\Builder` **orderBy** (*unknown \$orderBy*)

Sets a ORDER BY condition clause

```
<?php

$builder->orderBy('Robots.name');
$builder->orderBy(array('1', 'Robots.name'));
```

public `string|array` **getOrderBy** ()

Returns the set ORDER BY clause

public `Phalcon\Mvc\Model\Query\Builder` **having** (*unknown \$having*)

Sets a HAVING condition clause. You need to escape PHQL reserved words using [and] delimiters

```
<?php

$builder->having('SUM(Robots.price) > 0');
```

public string|array `getHaving()`

Return the current having clause

public Phalcon\Mvc\Model\Query\Builder `limit (unknown $limit, [unknown $offset])`

Sets a LIMIT clause, optionally a offset clause

```
<?php
```

```
$builder->limit(100);  
$builder->limit(100, 20);
```

public string|array `getLimit()`

Returns the current LIMIT clause

public Phalcon\Mvc\Model\Query\Builder `offset (unknown $offset)`

Sets an OFFSET clause

```
<?php
```

```
$builder->offset(30);
```

public string|array `getOffset()`

Returns the current OFFSET clause

public Phalcon\Mvc\Model\Query\Builder `groupBy (unknown $group)`

Sets a GROUP BY clause

```
<?php
```

```
$builder->groupBy(array('Robots.name'));
```

public string `getGroupBy()`

Returns the GROUP BY clause

public string `getPhql()`

Returns a PHQL statement built based on the builder parameters

public Phalcon\Mvc\Model\Query `getQuery()`

Returns the query built

2.58.167 Abstract class Phalcon\Mvc\Model\Query\Lang

PHQL is implemented as a parser (written in C) that translates syntax in that of the target RDBMS. It allows Phalcon to offer a unified SQL language to the developer, while internally doing all the work of translating PHQL instructions to the most optimal SQL instructions depending on the RDBMS type associated with a model. To achieve the highest performance possible, we wrote a parser that uses the same technology as SQLite. This technology provides a small in-memory parser with a very low memory footprint that is also thread-safe.

```
<?php
```

```
$intermediate = Phalcon\Mvc\Model\Query\Lang::parsePHQL("SELECT r.* FROM Robots r LIMIT 10");
```

Methods

public static *string* **parsePHQL** (*unknown* \$phql)

Parses a PHQL statement returning an intermediate representation (IR)

2.58.168 Class Phalcon\Mvc\Model\Query\Status

implements Phalcon\Mvc\Model\Query\StatusInterface

This class represents the status returned by a PHQL statement like INSERT, UPDATE or DELETE. It offers context information and the related messages produced by the model which finally executes the operations when it fails

```
<?php

$phql = "UPDATE Robots SET name = :name:, type = :type:, year = :year: WHERE id = :id:";
$status = $app->modelsManager->executeQuery($phql, array(
    'id' => 100,
    'name' => 'Astroy Boy',
    'type' => 'mechanical',
    'year' => 1959
));
//Check if the update was successful
if ($status->success() == true) {
    echo 'OK';
}
```

Methods

public __construct (*unknown* \$success, [*unknown* \$model])

public Phalcon\Mvc\ModelInterface **getModel** ()

Returns the model that executed the action

public Phalcon\Mvc\Model\MessageInterface [] **getMessages** ()

Returns the messages produced because of a failed operation

public *boolean* **success** ()

Allows to check if the executed operation was successful

2.58.169 Class Phalcon\Mvc\Model\Relation

implements Phalcon\Mvc\Model\RelationInterface

This class represents a relationship between two models

Constants

integer **BELONGS_TO**

integer **HAS_ONE**

integer **HAS_MANY**

integer **HAS_ONE_THROUGH**

integer **HAS_MANY_THROUGH**

integer **NO_ACTION**

integer **ACTION_RESTRICT**

integer **ACTION.Cascade**

Methods

public __construct (*unknown* \$type, *unknown* \$referencedModel, *unknown* \$fields, *unknown* \$referencedFields, [*unknown* \$options])

Phalcon\Mvc\Model\Relation constructor

public setIntermediateRelation (*unknown* \$intermediateFields, *unknown* \$intermediateModel, *unknown* \$intermediateReferencedFields)

Sets the intermediate model data for has-*through relations

public int getType ()

Returns the relation type

public string getReferencedModel ()

Returns the referenced model

public string|array getFields ()

Returns the fields

public string|array getReferencedFields ()

Returns the referenced fields

public string|array getOptions ()

Returns the options

public boolean isForeignKey ()

Check whether the relation act as a foreign key

public string|array getForeignKey ()

Returns the foreign key configuration

public array getParams ()

Returns parameters that must be always used when the related records are obtained

public boolean isThrough ()

Check whether the relation is a ‘many-to-many’ relation or not

public boolean isReusable ()

Check if records returned by getting belongs-to/has-many are implicitly cached during the current request

public string|array getIntermediateFields ()

Gets the intermediate fields for has-*through relations

public string getIntermediateModel ()

Gets the intermediate model for has-*through relations

public string|array getIntermediateReferencedFields ()
 Gets the intermediate referenced fields for has-*through relations

2.58.170 Abstract class Phalcon\\Mvc\\Model\\Resultset

implements Phalcon\\Mvc\\Model\\ResultsetInterface, Iterator, Traversable, SeekableIterator, Countable, ArrayAccess, Serializable

This component allows to Phalcon\\Mvc\\Model returns large resultsets with the minimum memory consumption Resultsets can be traversed using a standard foreach or a while statement. If a resultset is serialized it will dump all the rows into a big array. Then unserialize will retrieve the rows as they were before serializing.

```
<?php

//Using a standard foreach
$robots = Robots::find(array("type='virtual'", "order" => "name"));
foreach ($robots as $robot) {
    echo $robot->name, "\n";
}

//Using a while
$robots = Robots::find(array("type='virtual'", "order" => "name"));
$robots->rewind();
while ($robots->valid()) {
    $robot = $robots->current();
    echo $robot->name, "\n";
    $robots->next();
}
```

Constants

integer TYPE_RESULT_FULL
integer TYPE_RESULT_PARTIAL
integer HYDRATE_RECORDS
integer HYDRATE_OBJECTS
integer HYDRATE_ARRAYS

Methods

public next ()
 Moves cursor to next row in the resultset

public int key ()
 Gets pointer number of active row in the resultset

final public rewind ()
 Rewinds resultset to its beginning

final public seek (unknown \$position)
 Changes internal pointer to a specific position in the resultset

`final public int count ()`

Counts how many rows are in the resultset

`public boolean offsetExists (unknown $index)`

Checks whether offset exists in the resultset

`public Phalcon\Mvc\ModelInterface offsetGet (unknown $index)`

Gets row in a specific position of the resultset

`public offsetSet (unknown $index, unknown $value)`

Resultsets cannot be changed. It has only been implemented to meet the definition of the ArrayAccess interface

`public offsetUnset (unknown $offset)`

Resultsets cannot be changed. It has only been implemented to meet the definition of the ArrayAccess interface

`public int getType ()`

Returns the internal type of data retrieval that the resultset is using

`public Phalcon\Mvc\ModelInterface |boolean getFirst ()`

Get first row in the resultset

`public Phalcon\Mvc\ModelInterface | boolean getLast ()`

Get last row in the resultset

`public Phalcon\Mvc\Model\Resultset setIsFresh (unknown $isFresh)`

Set if the resultset is fresh or an old one cached

`public boolean isFresh ()`

Tell if the resultset is fresh or an old one cached

`public Phalcon\Mvc\Model\Resultset setHydrateMode (unknown $hydrateMode)`

Sets the hydration mode in the resultset

`public int getHydrateMode ()`

Returns the current hydration mode

`public Phalcon\Cache\BackendInterface getCache ()`

Returns the associated cache for the resultset

`final public Phalcon\Mvc\ModelInterface current ()`

Returns current row in the resultset

`public Phalcon\Mvc\Model\MessageInterface [] getMessages ()`

Returns the error messages produced by a batch operation

`public boolean update (unknown $data, [unknown $conditionCallback])`

Updates every record in the resultset

`public boolean delete ([unknown $conditionCallback])`

Deletes every record in the resultset

`public Phalcon\Mvc\Model [] filter (unknown $filter)`

Filters a resultset returning only those the developer requires

```
<?php

$filtered = $robots->filter(function($robot) {
    if ($robot->id < 3) {
        return $robot;
    }
});
```

abstract public **toArray** () inherited from Phalcon\Mvc\Model\ResultsetInterface

...

abstract public **valid** () inherited from Iterator

...

abstract public **serialize** () inherited from Serializable

...

abstract public **unserialize** (*unknown* \$serialized) inherited from Serializable

...

2.58.171 Class Phalcon\Mvc\Model\Resultset\Complex

extends abstract class Phalcon\Mvc\Model\Resultset

implements Serializable, ArrayAccess, Countable, SeekableIterator, Traversable, Iterator, Phalcon\Mvc\Model\ResultsetInterface

Complex resultsets may include complete objects and scalar values. This class builds every complex row as it is required

Constants

integer TYPE_RESULT_FULL

integer TYPE_RESULT_PARTIAL

integer HYDRATE_RECORDS

integer HYDRATE_OBJECTS

integer HYDRATE_ARRAYS

Methods

public __construct (*unknown* \$columnTypes, *unknown* \$result, [*unknown* \$cache])

Phalcon\Mvc\Model\Resultset\Complex constructor

public *boolean* valid ()

Check whether internal resource has rows to fetch

public *array* toArray ()

Returns a complete resultset as an array, if the resultset has a big number of rows it could consume more memory than currently it does.

public *string* serialize ()

Serializing a resultset will dump all related rows into a big array

public **unserialize** (*unknown* \$data)

Unserializing a resultset will allow to only works on the rows present in the saved state

public **next** () inherited from Phalcon\Mvc\Model\Resultset

Moves cursor to next row in the resultset

public *int* **key** () inherited from Phalcon\Mvc\Model\Resultset

Gets pointer number of active row in the resultset

final public **rewind** () inherited from Phalcon\Mvc\Model\Resultset

Rewinds resultset to its beginning

final public **seek** (*unknown* \$position) inherited from Phalcon\Mvc\Model\Resultset

Changes internal pointer to a specific position in the resultset

final public *int* **count** () inherited from Phalcon\Mvc\Model\Resultset

Counts how many rows are in the resultset

public *boolean* **offsetExists** (*unknown* \$index) inherited from Phalcon\Mvc\Model\Resultset

Checks whether offset exists in the resultset

public [Phalcon\Mvc\ModelInterface](#) **offsetGet** (*unknown* \$index) inherited from Phalcon\Mvc\Model\Resultset

Gets row in a specific position of the resultset

public **offsetSet** (*unknown* \$index, *unknown* \$value) inherited from Phalcon\Mvc\Model\Resultset

Resulsets cannot be changed. It has only been implemented to meet the definition of the ArrayAccess interface

public **offsetUnset** (*unknown* \$offset) inherited from Phalcon\Mvc\Model\Resultset

Resulsets cannot be changed. It has only been implemented to meet the definition of the ArrayAccess interface

public *int* **getType** () inherited from Phalcon\Mvc\Model\Resultset

Returns the internal type of data retrieval that the resultset is using

public [Phalcon\Mvc\ModelInterface](#) | *boolean* **getFirst** () inherited from Phalcon\Mvc\Model\Resultset

Get first row in the resultset

public [Phalcon\Mvc\ModelInterface](#) | *boolean* **getLast** () inherited from Phalcon\Mvc\Model\Resultset

Get last row in the resultset

public [Phalcon\Mvc\Model\Resultset](#) **setIsFresh** (*unknown* \$isFresh) inherited from Phalcon\Mvc\Model\Resultset

Set if the resultset is fresh or an old one cached

public *boolean* **isFresh** () inherited from Phalcon\Mvc\Model\Resultset

Tell if the resultset if fresh or an old one cached

public [Phalcon\Mvc\Model\Resultset](#) **setHydrateMode** (*unknown* \$hydrateMode) inherited from Phalcon\Mvc\Model\Resultset

Sets the hydration mode in the resultset

public *int* **getHydrateMode** () inherited from Phalcon\Mvc\Model\Resultset

Returns the current hydration mode

public [Phalcon\Cache\BackendInterface](#) **getCache** () inherited from [Phalcon\Mvc\Model\Resultset](#)
 Returns the associated cache for the resultset

final public [Phalcon\Mvc\ModelInterface](#) **current** () inherited from [Phalcon\Mvc\Model\Resultset](#)
 Returns current row in the resultset

public [Phalcon\Mvc\Model\MessageInterface](#) [] **getMessages** () inherited from [Phalcon\Mvc\Model\Resultset](#)
 Returns the error messages produced by a batch operation

public *boolean* **update** (*unknown* \$data, [*unknown* \$conditionCallback]) inherited from [Phalcon\Mvc\Model\Resultset](#)
 Updates every record in the resultset

public *boolean* **delete** ([*unknown* \$conditionCallback]) inherited from [Phalcon\Mvc\Model\Resultset](#)
 Deletes every record in the resultset

public [Phalcon\Mvc\Model](#) [] **filter** (*unknown* \$filter) inherited from [Phalcon\Mvc\Model\Resultset](#)
 Filters a resultset returning only those the developer requires

```
<?php

$filtered = $robots->filter(function($robot) {
    if ($robot->id < 3) {
        return $robot;
    }
});
```

2.58.172 Class Phalcon\Mvc\Model\Resultset\Simple

extends abstract class [Phalcon\Mvc\Model\Resultset](#)

implements Serializable, ArrayAccess, Countable, SeekableIterator, Traversable, Iterator, [Phalcon\Mvc\Model\ResultsetInterface](#)

Simple resultsets only contains a complete objects This class builds every complete object as it is required

Constants

integer **TYPE_RESULT_FULL**

integer **TYPE_RESULT_PARTIAL**

integer **HYDRATE_RECORDS**

integer **HYDRATE_OBJECTS**

integer **HYDRATE_ARRAYS**

Methods

public __construct (*unknown* \$columnMap, *unknown* \$model, *unknown* \$result, [*unknown* \$cache], [*unknown* \$keepSchemas])

Phalcon\Mvc\Model\Resultset\Simple constructor

public *boolean* **valid** ()

Check whether internal resource has rows to fetch

`public array toArray ([unknown $renameColumns])`

Returns a complete resultset as an array, if the resultset has a big number of rows it could consume more memory than currently it does. Export the resultset to an array couldn't be faster with a large number of records

`public string serialize ()`

Serializing a resultset will dump all related rows into a big array

`public unserialize (unknown $data)`

Unserializing a resultset will allow to only works on the rows present in the saved state

`public next () inherited from Phalcon\Mvc\Model\Resultset`

Moves cursor to next row in the resultset

`public int key () inherited from Phalcon\Mvc\Model\Resultset`

Gets pointer number of active row in the resultset

`final public rewind () inherited from Phalcon\Mvc\Model\Resultset`

Rewinds resultset to its beginning

`final public seek (unknown $position) inherited from Phalcon\Mvc\Model\Resultset`

Changes internal pointer to a specific position in the resultset

`final public int count () inherited from Phalcon\Mvc\Model\Resultset`

Counts how many rows are in the resultset

`public boolean offsetExists (unknown $index) inherited from Phalcon\Mvc\Model\Resultset`

Checks whether offset exists in the resultset

`public Phalcon\Mvc\ModelInterface offsetGet (unknown $index) inherited from Phalcon\Mvc\Model\Resultset`

Gets row in a specific position of the resultset

`public offsetSet (unknown $index, unknown $value) inherited from Phalcon\Mvc\Model\Resultset`

Resulsets cannot be changed. It has only been implemented to meet the definition of the ArrayAccess interface

`public offsetUnset (unknown $offset) inherited from Phalcon\Mvc\Model\Resultset`

Resulsets cannot be changed. It has only been implemented to meet the definition of the ArrayAccess interface

`public int getType () inherited from Phalcon\Mvc\Model\Resultset`

Returns the internal type of data retrieval that the resultset is using

`public Phalcon\Mvc\ModelInterface |boolean getFirst () inherited from Phalcon\Mvc\Model\Resultset`

Get first row in the resultset

`public Phalcon\Mvc\ModelInterface | boolean getLast () inherited from Phalcon\Mvc\Model\Resultset`

Get last row in the resultset

`public Phalcon\Mvc\Model\Resultset setIsFresh (unknown $isFresh) inherited from Phalcon\Mvc\Model\Resultset`

Set if the resultset is fresh or an old one cached

`public boolean isFresh () inherited from Phalcon\Mvc\Model\Resultset`

Tell if the resultset if fresh or an old one cached

public `Phalcon\Mvc\Model\Resultset` **setHydrateMode** (*unknown* \$hydrateMode) inherited from `Phalcon\Mvc\Model\Resultset`

Sets the hydration mode in the resultset

public *int* **getHydrateMode** () inherited from `Phalcon\Mvc\Model\Resultset`

Returns the current hydration mode

public `Phalcon\Cache\BackendInterface` **getCache** () inherited from `Phalcon\Mvc\Model\Resultset`

Returns the associated cache for the resultset

final public `Phalcon\Mvc\ModelInterface` **current** () inherited from `Phalcon\Mvc\Model\Resultset`

Returns current row in the resultset

public `Phalcon\Mvc\Model\MessageInterface` [] **getMessages** () inherited from `Phalcon\Mvc\Model\Resultset`

Returns the error messages produced by a batch operation

public *boolean* **update** (*unknown* \$data, [*unknown* \$conditionCallback]) inherited from `Phalcon\Mvc\Model\Resultset`

Updates every record in the resultset

public *boolean* **delete** ([*unknown* \$conditionCallback]) inherited from `Phalcon\Mvc\Model\Resultset`

Deletes every record in the resultset

public `Phalcon\Mvc\Model` [] **filter** (*unknown* \$filter) inherited from `Phalcon\Mvc\Model\Resultset`

Filters a resultset returning only those the developer requires

```
<?php

$filtered = $robots->filter(function($robot) {
    if ($robot->id < 3) {
        return $robot;
    }
});
```

2.58.173 Class Phalcon\Mvc\Model\Row

implements `ArrayAccess`, `Phalcon\Mvc\Model\ResultInterface`

This component allows `Phalcon\Mvc\Model` to return rows without an associated entity. This objects implements the `ArrayAccess` interface to allow access the object as `object->x` or `array[x]`.

Methods

public **setDirtyState** (*unknown* \$dirtyState)

Set the current object's state

public *boolean* **offsetExists** (*string|int* \$index)

Checks whether offset exists in the row

public *string|PhalconMvcModelInterface* **offsetGet** (*unknown* \$index)

Gets a record in a specific position of the row

public **offsetSet** (*unknown* \$index, *unknown* \$value)

Rows cannot be changed. It has only been implemented to meet the definition of the ArrayAccess interface

public **offsetUnset** (*unknown* \$offset)

Rows cannot be changed. It has only been implemented to meet the definition of the ArrayAccess interface

public *array* **toArray** ()

Returns the instance as an array representation

2.58.174 Class Phalcon\Mvc\Model\Transaction

implements Phalcon\Mvc\Model\TransactionInterface

Transactions are protective blocks where SQL statements are only permanent if they can all succeed as one atomic action. Phalcon\Transaction is intended to be used with Phalcon_Model_Base. Phalcon Transactions should be created using Phalcon\Transaction\Manager.

```
<?php

try {

    $manager = new \Phalcon\Mvc\Model\Transaction\Manager();

    $transaction = $manager->get();

    $robot = new Robots();
    $robot->setTransaction($transaction);
    $robot->name = 'WALL·E';
    $robot->created_at = date('Y-m-d');
    if ($robot->save() == false) {
        $transaction->rollback("Can't save robot");
    }

    $robotPart = new RobotParts();
    $robotPart->setTransaction($transaction);
    $robotPart->type = 'head';
    if ($robotPart->save() == false) {
        $transaction->rollback("Can't save robot part");
    }

    $transaction->commit();

} catch (Phalcon\Mvc\Model\Transaction\Failed $e) {
    echo 'Failed, reason: ', $e->getMessage();
}
```

Methods

public **__construct** (*unknown* \$dependencyInjector, [*unknown* \$autoBegin], [*unknown* \$service])

Phalcon\Mvc\Model\Transaction constructor

public **setTransactionManager** (*Phalcon\Mvc\Model\Transaction\ManagerInterface* \$manager)

Sets transaction manager related to the transaction

public *boolean* **begin** ()

Starts the transaction

```
public boolean commit ()  
Commits the transaction  
public boolean rollback ([unknown $rollbackMessage], [unknown $rollbackRecord])  
Rollbacks the transaction  
public Phalcon\Db\AdapterInterface getConnection ()  
Returns the connection related to transaction  
public setIsNewTransaction (unknown $isNew)  
Sets if is a reused transaction or new once  
public setRollbackOnAbort (boolean $rollbackOnAbort)  
Sets flag to rollback on abort the HTTP connection  
public boolean isManaged ()  
Checks whether transaction is managed by a transaction manager  
public array getMessages ()  
Returns validations messages from last save try  
public boolean isValid ()  
Checks whether internal connection is under an active transaction  
public setRollbackedRecord (unknown $record)  
Sets object which generates rollback action
```

2.58.175 Class Phalcon\Mvc\Model\Transaction\Exception

extends class Phalcon\Mvc\Model\Exception

Methods

```
final private Exception __clone () inherited from Exception  
Clone the exception  
public __construct ([string $message], [int $code], [Exception $previous]) inherited from Exception  
Exception constructor  
final public string getMessage () inherited from Exception  
Gets the Exception message  
final public int getCode () inherited from Exception  
Gets the Exception code  
final public string getFile () inherited from Exception  
Gets the file in which the exception occurred  
final public int getLine () inherited from Exception  
Gets the line in which the exception occurred  
final public array getTrace () inherited from Exception
```

Gets the stack trace

final public *Exception* **getPrevious** () inherited from *Exception*

Returns previous *Exception*

final public *Exception* **getTraceAsString** () inherited from *Exception*

Gets the stack trace as a string

public *string* **_toString** () inherited from *Exception*

String representation of the exception

2.58.176 Class Phalcon\\Mvc\\Model\\Transaction\\Failed

extends class Phalcon\\Mvc\\Model\\Transaction\\Exception

This class will be thrown to exit a try/catch block for isolated transactions

Methods

public **__construct** (*unknown* \$message, [*unknown* \$record])

Phalcon\\Mvc\\Model\\Transaction\\Failed constructor

public Phalcon\\Mvc\\Model\\MessageInterface [] **getRecordMessages** ()

Returns validation record messages which stop the transaction

public Phalcon\\Mvc\\ModelInterface **getRecord** ()

Returns validation record messages which stop the transaction

final private *Exception* **_clone** () inherited from *Exception*

Clone the exception

final public *string* **getMessage** () inherited from *Exception*

Gets the *Exception* message

final public *int* **getCode** () inherited from *Exception*

Gets the *Exception* code

final public *string* **getFile** () inherited from *Exception*

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from *Exception*

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from *Exception*

Gets the stack trace

final public *Exception* **getPrevious** () inherited from *Exception*

Returns previous *Exception*

final public *Exception* **getTraceAsString** () inherited from *Exception*

Gets the stack trace as a string

public *string* **_toString** () inherited from *Exception*

String representation of the exception

2.58.177 Class Phalcon\Mvc\Model\Transaction\Manager

implements Phalcon\Mvc\Model\Transaction\ManagerInterface, Phalcon\Di\InjectionAwareInterface

A transaction acts on a single database connection. If you have multiple class-specific databases, the transaction will not protect interaction among them. This class manages the objects that compose a transaction. A transaction produces a unique connection that is passed to every object part of the transaction.

```
<?php

try {

    use Phalcon\Mvc\Model\Transaction\Manager as TransactionManager;

    $transactionManager = new TransactionManager();

    $transaction = $transactionManager->get();

    $robot = new Robots();
    $robot->setTransaction($transaction);
    $robot->name = 'WALL·E';
    $robot->created_at = date('Y-m-d');
    if($robot->save() == false) {
        $transaction->rollback("Can't save robot");
    }

    $robotPart = new RobotParts();
    $robotPart->setTransaction($transaction);
    $robotPart->type = 'head';
    if($robotPart->save() == false) {
        $transaction->rollback("Can't save robot part");
    }

    $transaction->commit();

} catch (Phalcon\Mvc\Model\Transaction\Failed $e) {
    echo 'Failed, reason: ', $e->getMessage();
}
```

Methods

public __construct ([*unknown* \$dependencyInjector])

Phalcon\Mvc\Model\Transaction\Manager constructor

public **setDI** (*unknown* \$dependencyInjector)

Sets the dependency injection container

public **Phalcon\DiInterface getDI** ()

Returns the dependency injection container

public **Phalcon\Mvc\Model\Transaction\Manager setDbService** (*unknown* \$service)

Sets the database service used to run the isolated transactions

public *string* **getDbService** ()

Returns the database service used to isolate the transaction

public [Phalcon\Mvc\Model\Transaction\Manager](#) **setRollbackPendent** (*unknown* \$rollbackPendent)

Set if the transaction manager must register a shutdown function to clean up pendent transactions

public *boolean* **getRollbackPendent** ()

Check if the transaction manager is registering a shutdown function to clean up pendent transactions

public *boolean* **has** ()

Checks whether the manager has an active transaction

public [Phalcon\Mvc\Model\TransactionInterface](#) **get** ([*unknown* \$autoBegin])

Returns a new [\Phalcon\ Mvc\ Model\ Transaction](#) or an already created once This method registers a shutdown function to rollback active connections

public [Phalcon\Mvc\Model\TransactionInterface](#) **getOrCreateTransaction** ([*unknown* \$autoBegin])

Create/Returns a new transaction or an existing one

public **rollbackPendent** ()

Rollbacks active transactions within the manager

public **commit** ()

Commmits active transactions within the manager

public **rollback** ([*unknown* \$collect])

Rollbacks active transactions within the manager Collect will remove the transaction from the manager

public **notifyRollback** (*unknown* \$transaction)

Notifies the manager about a rollbacked transaction

public **notifyCommit** (*unknown* \$transaction)

Notifies the manager about a committed transaction

protected **_collectTransaction** (*unknown* \$transaction)

Removes transactions from the TransactionManager

public **collectTransactions** ()

Remove all the transactions from the manager

2.58.178 Class [Phalcon\Mvc\Model\ValidationFailed](#)

extends class [Phalcon\Mvc\Model\Exception](#)

Methods

final private *Exception* **__clone** () inherited from *Exception*

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from *Exception*

Exception constructor

final public *string* **getMessage** () inherited from Exception
Gets the Exception message

final public *int* **getCode** () inherited from Exception
Gets the Exception code

final public *string* **getFile** () inherited from Exception
Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception
Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception
Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception
Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception
Gets the stack trace as a string

public *string* **__toString** () inherited from Exception
String representation of the exception

2.58.179 Abstract class Phalcon\Mvc\Model\Validator

This is a base class for Phalcon\Mvc\Model validators

Methods

public **__construct** (*unknown* \$options)
Phalcon\Mvc\Model\Validator constructor

protected **appendMessage** (*unknown* \$message, [*unknown* \$field], [*unknown* \$type])
Appends a message to the validator

public *array* **getMessages** ()
Returns messages generated by the validator

protected *array* **getOptions** ()
Returns all the options from the validator

protected *mixed* **getOption** (*unknown* \$option)
Returns an option

protected *boolean* **isSetOption** (*unknown* \$option)
Check whether a option has been defined in the validator options

2.58.180 Class Phalcon\\Mvc\\Model\\Validator\\Email

extends abstract class Phalcon\\Mvc\\Model\\Validator

implements Phalcon\\Mvc\\Model\\ValidatorInterface

Allows to validate if email fields has correct values

```
<?php

use Phalcon\\Mvc\\Model\\Validator\\Email as EmailValidator;

class Subscriptors extends \\Phalcon\\Mvc\\Model
{

    public function validation()
    {
        $this->validate(new EmailValidator(array(
            'field' => 'electronic_mail'
        )));
        if ($this->validationHasFailed() == true) {
            return false;
        }
    }
}
```

Methods

public boolean validate (*unknown* \$record)

Executes the validator

public __construct (*unknown* \$options) inherited from Phalcon\\Mvc\\Model\\Validator

Phalcon\\Mvc\\Model\\Validator constructor

protected appendMessage (*unknown* \$message, [*unknown* \$field], [*unknown* \$type]) inherited from Phalcon\\Mvc\\Model\\Validator

Appends a message to the validator

public array getMessages () inherited from Phalcon\\Mvc\\Model\\Validator

Returns messages generated by the validator

protected array getOptions () inherited from Phalcon\\Mvc\\Model\\Validator

Returns all the options from the validator

protected mixed getOption (*unknown* \$option) inherited from Phalcon\\Mvc\\Model\\Validator

Returns an option

protected boolean isSetOption (*unknown* \$option) inherited from Phalcon\\Mvc\\Model\\Validator

Check whether a option has been defined in the validator options

2.58.181 Class Phalcon\\Mvc\\Model\\Validator\\Exclusionin

extends abstract class Phalcon\\Mvc\\Model\\Validator

implements [Phalcon\Mvc\Model\ValidatorInterface](#)

[Phalcon\Mvc\Model\Validator\ExclusionIn](#) Check if a value is not included into a list of values

```
<?php

use Phalcon\Mvc\Model\Validator\ExclusionIn as ExclusionInValidator;

class Subscriptors extends \Phalcon\Mvc\Model
{

    public function validation()
    {
        $this->validate(new ExclusionInValidator(array(
            'field' => 'status',
            'domain' => array('A', 'I')
        )));
        if ($this->validationHasFailed() == true) {
            return false;
        }
    }
}
```

Methods

public boolean validate (*unknown* \$record)

Executes the validator

public __construct (*unknown* \$options) inherited from [Phalcon\Mvc\Model\Validator](#)

[Phalcon\Mvc\Model\Validator](#) constructor

protected appendMessage (*unknown* \$message, [*unknown* \$field], [*unknown* \$type]) inherited from [Phalcon\Mvc\Model\Validator](#)

Appends a message to the validator

public array getMessages () inherited from [Phalcon\Mvc\Model\Validator](#)

Returns messages generated by the validator

protected array getOptions () inherited from [Phalcon\Mvc\Model\Validator](#)

Returns all the options from the validator

protected mixed getOption (*unknown* \$option) inherited from [Phalcon\Mvc\Model\Validator](#)

Returns an option

protected boolean isSetOption (*unknown* \$option) inherited from [Phalcon\Mvc\Model\Validator](#)

Check whether a option has been defined in the validator options

2.58.182 Class [Phalcon\Mvc\Model\Validator\Inclusionin](#)

extends abstract class [Phalcon\Mvc\Model\Validator](#)

implements [Phalcon\Mvc\Model\ValidatorInterface](#)

[Phalcon\Mvc\Model\Validator\InclusionIn](#) Check if a value is included into a list of values

```
<?php

use Phalcon\Mvc\Model\Validator\InclusionIn as InclusionInValidator;

class Subscriptors extends \Phalcon\Mvc\Model
{

    public function validation()
    {
        $this->validate(new InclusionInValidator([
            "field" => 'status',
            'domain' => array('A', 'I')
        )));
        if ($this->validationHasFailed() == true) {
            return false;
        }
    }

}
```

Methods

public *boolean validate (unknown \$record)*

Executes validator

public *__construct (unknown \$options)* inherited from Phalcon\Mvc\Model\Validator

Phalcon\Mvc\Model\Validator constructor

protected *appendMessage (unknown \$message, [unknown \$field], [unknown \$type])* inherited from Phalcon\Mvc\Model\Validator

Appends a message to the validator

public *array getMessages ()* inherited from Phalcon\Mvc\Model\Validator

Returns messages generated by the validator

protected *array getOptions ()* inherited from Phalcon\Mvc\Model\Validator

Returns all the options from the validator

protected *mixed getOption (unknown \$option)* inherited from Phalcon\Mvc\Model\Validator

Returns an option

protected *boolean isSetOption (unknown \$option)* inherited from Phalcon\Mvc\Model\Validator

Check whether a option has been defined in the validator options

2.58.183 Class Phalcon\Mvc\Model\Validator\Numericality

extends abstract class Phalcon\Mvc\Model\Validator

implements Phalcon\Mvc\Model\ValidatorInterface

Allows to validate if a field has a valid numeric format

```
<?php

use Phalcon\Mvc\Model\Validator\Numericality as NumericalityValidator;

class Products extends \Phalcon\Mvc\Model
{

    public function validation()
    {
        $this->validate(new NumericalityValidator(array(
            "field" => 'price'
        )));
        if ($this->validationHasFailed() == true) {
            return false;
        }
    }
}
```

Methods

public boolean validate (*unknown* \$record)

Executes the validator

public __construct (*unknown* \$options) inherited from Phalcon\Mvc\Model\Validator

Phalcon\Mvc\Model\Validator constructor

protected appendMessage (*unknown* \$message, [*unknown* \$field], [*unknown* \$type]) inherited from Phalcon\Mvc\Model\Validator

Appends a message to the validator

public array getMessages () inherited from Phalcon\Mvc\Model\Validator

Returns messages generated by the validator

protected array getOptions () inherited from Phalcon\Mvc\Model\Validator

Returns all the options from the validator

protected mixed getOption (*unknown* \$option) inherited from Phalcon\Mvc\Model\Validator

Returns an option

protected boolean isSetOption (*unknown* \$option) inherited from Phalcon\Mvc\Model\Validator

Check whether a option has been defined in the validator options

2.58.184 Class Phalcon\Mvc\Model\Validator\PresenceOf

extends abstract class Phalcon\Mvc\Model\Validator

implements Phalcon\Mvc\Model\ValidatorInterface

Allows to validate if a filed have a value different of null and empty string ("")

```
<?php

use Phalcon\Mvc\Model\Validator\PresenceOf;
```

```
class Subscriptors extends \Phalcon\Mvc\Model
{

    public function validation()
    {
        $this->validate(new PresenceOf(array(
            "field" => 'name',
            "message" => 'The name is required'
        )));
        if ($this->validationHasFailed() == true) {
            return false;
        }
    }
}
```

Methods

public **boolean validate** (*unknown* \$record)

Executes the validator

public **__construct** (*unknown* \$options) inherited from Phalcon\Mvc\Model\Validator

Phalcon\Mvc\Model\Validator constructor

protected **appendMessage** (*unknown* \$message, [*unknown* \$field], [*unknown* \$type]) inherited from Phalcon\Mvc\Model\Validator

Appends a message to the validator

public **array getMessages** () inherited from Phalcon\Mvc\Model\Validator

Returns messages generated by the validator

protected **array getOptions** () inherited from Phalcon\Mvc\Model\Validator

Returns all the options from the validator

protected **mixed getOption** (*unknown* \$option) inherited from Phalcon\Mvc\Model\Validator

Returns an option

protected **boolean isSetOption** (*unknown* \$option) inherited from Phalcon\Mvc\Model\Validator

Check whether a option has been defined in the validator options

2.58.185 Class Phalcon\Mvc\Model\Validator\Regex

extends abstract class Phalcon\Mvc\Model\Validator

implements Phalcon\Mvc\Model\ValidatorInterface

Allows validate if the value of a field matches a regular expression

```
<?php

use Phalcon\Mvc\Model\Validator\Regex as RegexValidator;

class Subscriptors extends \Phalcon\Mvc\Model
{
```

```

public function validation()
{
    this->validate(new RegexValidator(array(
        "field" => 'created_at',
        'pattern' => '/^([0-9]{4})[-\\/](0[1-9]|1[0-2])[-\\/](0[1-9]|1[0-2])[0-9]{3}[01]')/');
}
if (this->validationHasFailed() == true) {
    return false;
}
}
}

```

Methods

public boolean validate (unknown \$record)

Executes the validator

public __construct (unknown \$options) inherited from Phalcon\Mvc\Model\Validator

Phalcon\Mvc\Model\Validator constructor

protected appendMessage (unknown \$message, [unknown \$field], [unknown \$type]) inherited from Phalcon\Mvc\Model\Validator

Appends a message to the validator

public array getMessages () inherited from Phalcon\Mvc\Model\Validator

Returns messages generated by the validator

protected array getOptions () inherited from Phalcon\Mvc\Model\Validator

Returns all the options from the validator

protected mixed getOption (unknown \$option) inherited from Phalcon\Mvc\Model\Validator

Returns an option

protected boolean isSetOption (unknown \$option) inherited from Phalcon\Mvc\Model\Validator

Check whether a option has been defined in the validator options

2.58.186 Class Phalcon\Mvc\Model\Validator\StringLength

extends abstract class Phalcon\Mvc\Model\Validator

implements Phalcon\Mvc\Model\ValidatorInterface

Simply validates specified string length constraints

```

<?php

use Phalcon\Mvc\Model\Validator\StringLength as StringLengthValidator;

class Subscriptors extends \Phalcon\Mvc\Model
{

public function validation()
{
}

```

```
        $this->validate(new StringLengthValidator(array(
            "field" => 'name_last',
            'max' => 50,
            'min' => 2,
            'messageMaximum' => 'We don\'t like really long names',
            'messageMinimum' => 'We want more than just their initials'
        )));
        if ($this->validationHasFailed() == true) {
            return false;
        }
    }
}
```

Methods

public *boolean validate* (*unknown \$record*)

Executes the validator

public *__construct* (*unknown \$options*) inherited from Phalcon\Mvc\Model\Validator

Phalcon\Mvc\Model\Validator constructor

protected *appendMessage* (*unknown \$message, [unknown \$field], [unknown \$type]*) inherited from Phalcon\Mvc\Model\Validator

Appends a message to the validator

public *array getMessages* () inherited from Phalcon\Mvc\Model\Validator

Returns messages generated by the validator

protected *array getOptions* () inherited from Phalcon\Mvc\Model\Validator

Returns all the options from the validator

protected *mixed getOption* (*unknown \$option*) inherited from Phalcon\Mvc\Model\Validator

Returns an option

protected *boolean isSetOption* (*unknown \$option*) inherited from Phalcon\Mvc\Model\Validator

Check whether a option has been defined in the validator options

2.58.187 Class Phalcon\Mvc\Model\Validator\Uniqueness

extends abstract class Phalcon\Mvc\Model\Validator

implements Phalcon\Mvc\Model\ValidatorInterface

Validates that a field or a combination of a set of fields are not present more than once in the existing records of the related table

```
<?php

use Phalcon\Mvc\Model\Validator\Uniqueness as Uniqueness;

class Subscribers extends \Phalcon\Mvc\Model
{
```

```

public function validation()
{
    $this->validate(new Uniqueness(array
        "field" => 'email'
    ));
    if ($this->validationHasFailed() == true) {
        return false;
    }
}
}

```

Methods

public boolean validate (unknown \$record)

Executes the validator

public __construct (unknown \$options) inherited from Phalcon\Mvc\Model\Validator

Phalcon\Mvc\Model\Validator constructor

protected appendMessage (unknown \$message, [unknown \$field], [unknown \$type]) inherited from Phalcon\Mvc\Model\Validator

Appends a message to the validator

public array getMessages () inherited from Phalcon\Mvc\Model\Validator

Returns messages generated by the validator

protected array getOptions () inherited from Phalcon\Mvc\Model\Validator

Returns all the options from the validator

protected mixed getOption (unknown \$option) inherited from Phalcon\Mvc\Model\Validator

Returns an option

protected boolean isSetOption (unknown \$option) inherited from Phalcon\Mvc\Model\Validator

Check whether a option has been defined in the validator options

2.58.188 Class Phalcon\Mvc\Model\Validator\Url

extends abstract class Phalcon\Mvc\Model\Validator

implements Phalcon\Mvc\Model\ValidatorInterface

Allows to validate if a field has a url format

```

<?php

use Phalcon\Mvc\Model\Validator\Url as UrlValidator;

class Posts extends \Phalcon\Mvc\Model
{

    public function validation()
    {
        this->validate(new UrlValidator(array

```

```
        'field' => 'source_url'
    ));
if ($this->validationHasFailed() == true) {
    return false;
}
}

}
```

Methods

public boolean validate (*unknown* \$record)

Executes the validator

public __construct (*unknown* \$options) inherited from Phalcon\Mvc\Model\Validator

Phalcon\Mvc\Model\Validator constructor

protected appendMessage (*unknown* \$message, [*unknown* \$field], [*unknown* \$type]) inherited from Phalcon\Mvc\Model\Validator

Appends a message to the validator

public array getMessages () inherited from Phalcon\Mvc\Model\Validator

Returns messages generated by the validator

protected array getOptions () inherited from Phalcon\Mvc\Model\Validator

Returns all the options from the validator

protected mixed getOption (*unknown* \$option) inherited from Phalcon\Mvc\Model\Validator

Returns an option

protected boolean isSetOption (*unknown* \$option) inherited from Phalcon\Mvc\Model\Validator

Check whether a option has been defined in the validator options

2.58.189 Class Phalcon\Mvc\Router

implements Phalcon\Di\InjectionAwareInterface, Phalcon\Mvc\RouterInterface

Phalcon\Mvc\Router is the standard framework router. Routing is the process of taking a URI endpoint (that part of the URI which comes after the base URL) and decomposing it into parameters to determine which module, controller, and action of that controller should receive the request

```
<?php

$router = new Router();

$router->add(
    "/documentation/{chapter}/{name}.{type:[a-z]+}",
    array(
        "controller" => "documentation",
        "action"      => "show"
    )
);
```

```
$router->handle();

echo $router->getControllerName();
```

Constants

integer **URI_SOURCE_GET_URL**

integer **URI_SOURCE_SERVER_REQUEST_URI**

Methods

public __construct ([*unknown* \$defaultRoutes])

Phalcon\Mvc\Router constructor

public setDI (*unknown* \$dependencyInjector)

Sets the dependency injector

public getDI ()

Returns the internal dependency injector

public getRewriteUri ()

Get rewrite info. This info is read from `$_GET['_url']`. This returns '/' if the rewrite information cannot be read

public setUriSource (*unknown* \$uriSource)

Sets the URI source. One of the `URI_SOURCE_*` constants

```
<?php

$router->setUriSource (Router::URI_SOURCE_SERVER_REQUEST_URI);
```

public removeExtraSlashes (*unknown* \$remove)

Set whether router must remove the extra slashes in the handled routes

public setDefaultNamespace (*unknown* \$namespaceName)

Sets the name of the default namespace

public setDefaultModule (*unknown* \$moduleName)

Sets the name of the default module

public setDefaultController (*unknown* \$controllerName)

Sets the default controller name

public setDefaultAction (*unknown* \$actionName)

Sets the default action name

public setDefaults (*unknown* \$defaults)

Sets an array of default paths. If a route is missing a path the router will use the defined here. This method must not be used to set a 404 route

```
<?php  
  
$router->setDefaults(array(  
    'module' => 'common',  
    'action' => 'index'  
) );
```

public **handle** ([*unknown \$uri*])

Handles routing information received from the rewrite engine

```
<?php  
  
//Read the info from the rewrite engine  
$router->handle();  
  
//Manually passing an URL  
$router->handle('/posts/edit/1');
```

public **Phalcon\Mvc\Router\Route add** (*unknown \$pattern*, [*unknown \$paths*], [*unknown \$httpMethods*])

Adds a route to the router without any HTTP constraint

```
<?php  
  
$router->add('/about', 'About::index');
```

public **addGet** (*unknown \$pattern*, [*unknown \$paths*])

Adds a route to the router that only match if the HTTP method is GET

public **addPost** (*unknown \$pattern*, [*unknown \$paths*])

Adds a route to the router that only match if the HTTP method is POST

public **addPut** (*unknown \$pattern*, [*unknown \$paths*])

Adds a route to the router that only match if the HTTP method is PUT

public **Phalcon\Mvc\Router\Route addPatch** (*unknown \$pattern*, [*unknown \$paths*])

Adds a route to the router that only match if the HTTP method is PATCH

public **Phalcon\Mvc\Router\Route addDelete** (*unknown \$pattern*, [*unknown \$paths*])

Adds a route to the router that only match if the HTTP method is DELETE

public **Phalcon\Mvc\Router\Route addOptions** (*unknown \$pattern*, [*unknown \$paths*])

Add a route to the router that only match if the HTTP method is OPTIONS

public **Phalcon\Mvc\Router\Route addHead** (*unknown \$pattern*, [*unknown \$paths*])

Adds a route to the router that only match if the HTTP method is HEAD

public **Phalcon\Mvc\Router mount** (*unknown \$group*)

Mounts a group of routes in the router

public **notFound** (*unknown \$paths*)

Set a group of paths to be returned when none of the defined routes are matched

public **clear** ()

Removes all the pre-defined routes

```

public getNamespaceName ()
    Returns the processed namespace name

public getModuleName ()
    Returns the processed module name

public getControllerName ()
    Returns the processed controller name

public getActionName ()
    Returns the processed action name

public getParams ()
    Returns the processed parameters

public getMatchedRoute ()
    Returns the route that matches the handled URI

public getMatches ()
    Returns the sub expressions in the regular expression matched

public wasMatched ()
    Checks if the router matches any of the defined routes

public Phalcon\Mvc\Router\Route [] getRoutes ()
    Returns all the routes defined in the router

public getRouteById (unknown $id)
    Returns a route object by its id

public getRouteByName (unknown $name)
    Returns a route object by its name

public isExactControllerName ()
    Returns whether controller name should not be mangled

```

2.58.190 Class Phalcon\Mvc\Router\Annotations

extends class Phalcon\Mvc\Router

implements Phalcon\Mvc\RouterInterface, Phalcon\Di\InjectionAwareInterface

A router that reads routes annotations from classes/resources

```

<?php

$di['router'] = function() {

    //Use the annotations router
    $router = new Annotations(false);

    //This will do the same as above but only if the handled uri starts with /robots
    $router->addResource('Robots', '/robots');
}

```

```
    return $router;
};
```

Constants

integer **URI_SOURCE_GET_URL**

integer **URI_SOURCE_SERVER_REQUEST_URI**

Methods

public Phalcon\Mvc\Router\Annotations addResource (*unknown* \$handler, [*unknown* \$prefix])

Adds a resource to the annotations handler A resource is a class that contains routing annotations

public Phalcon\Mvc\Router\Annotations addModuleResource (*unknown* \$module, *unknown* \$handler, [*unknown* \$prefix])

Adds a resource to the annotations handler A resource is a class that contains routing annotations The class is located in a module

public handle ([*unknown* \$uri])

Produce the routing parameters from the rewrite information

public processControllerAnnotation (*unknown* \$handler, *unknown* \$annotation)

Checks for annotations in the controller docblock

public processActionAnnotation (*unknown* \$module, *unknown* \$namespaceName, *unknown* \$controller, *unknown* \$action, *unknown* \$annotation)

Checks for annotations in the public methods of the controller

public setControllerSuffix (*unknown* \$controllerSuffix)

Changes the controller class suffix

public setActionSuffix (*unknown* \$actionSuffix)

Changes the action method suffix

public array getResources ()

Return the registered resources

public __construct ([*unknown* \$defaultRoutes]) inherited from Phalcon\Mvc\Router

Phalcon\Mvc\Router constructor

public setDI (*unknown* \$dependencyInjector) inherited from Phalcon\Mvc\Router

Sets the dependency injector

public getDI () inherited from Phalcon\Mvc\Router

Returns the internal dependency injector

public getRewriteUri () inherited from Phalcon\Mvc\Router

Get rewrite info. This info is read from \$_GET['url']. This returns '/' if the rewrite information cannot be read

public setUriSource (*unknown* \$uriSource) inherited from Phalcon\Mvc\Router

Sets the URI source. One of the URI_SOURCE_* constants

```
<?php
$router->setUriSource(Router::URI_SOURCE_SERVER_REQUEST_URI);
```

public removeExtraSlashes (*unknown \$remove*) inherited from Phalcon\Mvc\Router

Set whether router must remove the extra slashes in the handled routes

public setDefaultNamespace (*unknown \$namespaceName*) inherited from Phalcon\Mvc\Router

Sets the name of the default namespace

public setDefaultModule (*unknown \$moduleName*) inherited from Phalcon\Mvc\Router

Sets the name of the default module

public setDefaultController (*unknown \$controllerName*) inherited from Phalcon\Mvc\Router

Sets the default controller name

public setDefaultAction (*unknown \$actionName*) inherited from Phalcon\Mvc\Router

Sets the default action name

public setDefaults (*unknown \$defaults*) inherited from Phalcon\Mvc\Router

Sets an array of default paths. If a route is missing a path the router will use the defined here This method must not be used to set a 404 route

```
<?php
$router->setDefaults(array(
    'module' => 'common',
    'action' => 'index'
));
```

public Phalcon\Mvc\Router\Route add (*unknown \$pattern, [unknown \$paths], [unknown \$httpMethods]*) inherited from Phalcon\Mvc\Router

Adds a route to the router without any HTTP constraint

```
<?php
$router->add('/about', 'About::index');
```

public addGet (*unknown \$pattern, [unknown \$paths]*) inherited from Phalcon\Mvc\Router

Adds a route to the router that only match if the HTTP method is GET

public addPost (*unknown \$pattern, [unknown \$paths]*) inherited from Phalcon\Mvc\Router

Adds a route to the router that only match if the HTTP method is POST

public addPut (*unknown \$pattern, [unknown \$paths]*) inherited from Phalcon\Mvc\Router

Adds a route to the router that only match if the HTTP method is PUT

public Phalcon\Mvc\Router\Route addPatch (*unknown \$pattern, [unknown \$paths]*) inherited from Phalcon\Mvc\Router

Adds a route to the router that only match if the HTTP method is PATCH

public Phalcon\Mvc\Router\Route addDelete (*unknown \$pattern, [unknown \$paths]*) inherited from Phalcon\Mvc\Router

Adds a route to the router that only match if the HTTP method is DELETE

public `Phalcon\Mvc\Router\Route` **addOptions** (*unknown* \$pattern, [*unknown* \$paths]) inherited from `Phalcon\Mvc\Router`

Add a route to the router that only match if the HTTP method is OPTIONS

public `Phalcon\Mvc\Router\Route` **addHead** (*unknown* \$pattern, [*unknown* \$paths]) inherited from `Phalcon\Mvc\Router`

Adds a route to the router that only match if the HTTP method is HEAD

public `Phalcon\Mvc\Router` **mount** (*unknown* \$group) inherited from `Phalcon\Mvc\Router`

Mounts a group of routes in the router

public **notFound** (*unknown* \$paths) inherited from `Phalcon\Mvc\Router`

Set a group of paths to be returned when none of the defined routes are matched

public **clear** () inherited from `Phalcon\Mvc\Router`

Removes all the pre-defined routes

public **getNamespaceName** () inherited from `Phalcon\Mvc\Router`

Returns the processed namespace name

public **getModuleName** () inherited from `Phalcon\Mvc\Router`

Returns the processed module name

public **getControllerName** () inherited from `Phalcon\Mvc\Router`

Returns the processed controller name

public **getActionName** () inherited from `Phalcon\Mvc\Router`

Returns the processed action name

public **getParams** () inherited from `Phalcon\Mvc\Router`

Returns the processed parameters

public **getMatchedRoute** () inherited from `Phalcon\Mvc\Router`

Returns the route that matches the handled URI

public **getMatches** () inherited from `Phalcon\Mvc\Router`

Returns the sub expressions in the regular expression matched

public **wasMatched** () inherited from `Phalcon\Mvc\Router`

Checks if the router matches any of the defined routes

public `Phalcon\Mvc\Router\Route` [] **getRoutes** () inherited from `Phalcon\Mvc\Router`

Returns all the routes defined in the router

public **getRouteById** (*unknown* \$id) inherited from `Phalcon\Mvc\Router`

Returns a route object by its id

public **getRouteByName** (*unknown* \$name) inherited from `Phalcon\Mvc\Router`

Returns a route object by its name

public **isExactControllerName** () inherited from `Phalcon\Mvc\Router`

Returns whether controller name should not be mangled

2.58.191 Class Phalcon\Mvc\Router\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception

Gets the stack trace as a string

public *string* **__toString** () inherited from Exception

String representation of the exception

2.58.192 Class Phalcon\Mvc\Router\Group

Helper class to create a group of routes with common attributes

```
<?php

$router = new \Phalcon\Mvc\Router();

//Create a group with a common module and controller
$blog = new Group(array(
    'module' => 'blog',
    'controller' => 'index'
));

//All the routes start with /blog
$blog->setPrefix('/blog');
```

```
//Add a route to the group
$blog->add('/save', array(
    'action' => 'save'
));

//Add another route to the group
$blog->add('/edit/{id}', array(
    'action' => 'edit'
));

//This route maps to a controller different than the default
$blog->add('/blog', array(
    'controller' => 'about',
    'action' => 'index'
));

//Add the group to the router
$router->mount($blog);
```

Methods

public __construct ([*unknown* \$paths])

Phalcon\Mvc\Router\Group constructor

public Phalcon\Mvc\Router\Group setHostname (*unknown* \$hostname)

Set a hostname restriction for all the routes in the group

public string getHostname ()

Returns the hostname restriction

public Phalcon\Mvc\Router\Group setPrefix (*unknown* \$prefix)

Set a common uri prefix for all the routes in this group

public string getPrefix ()

Returns the common prefix for all the routes

public Phalcon\Mvc\Router\Group beforeMatch (*unknown* \$beforeMatch)

Set a before-match condition for the whole group

public string getBeforeMatch ()

Returns the before-match condition if any

public Phalcon\Mvc\Router\Group setPaths (*unknown* \$paths)

Set common paths for all the routes in the group

public array|string getPaths ()

Returns the common paths defined for this group

public Phalcon\Mvc\Router\Route [] getRoutes ()

Returns the routes added to the group

protected Phalcon\Mvc\Router\Route _addRoute (*unknown* \$pattern, [*unknown* \$paths], [*unknown* \$httpMethods])

Adds a route applying the common attributes

public Phalcon\Mvc\Router\Route add (*unknown* \$pattern, [*unknown* \$paths], [*unknown* \$httpMethods])

Adds a route to the router on any HTTP method

```
<?php
```

```
router->add('/about', 'About::index');
```

public Phalcon\Mvc\Router\Route addGet (*unknown* \$pattern, [*unknown* \$paths])

Adds a route to the router that only match if the HTTP method is GET

public Phalcon\Mvc\Router\Route addPost (*unknown* \$pattern, [*unknown* \$paths])

Adds a route to the router that only match if the HTTP method is POST

public Phalcon\Mvc\Router\Route addPut (*unknown* \$pattern, [*unknown* \$paths])

Adds a route to the router that only match if the HTTP method is PUT

public Phalcon\Mvc\Router\Route addPatch (*unknown* \$pattern, [*unknown* \$paths])

Adds a route to the router that only match if the HTTP method is PATCH

public Phalcon\Mvc\Router\Route addDelete (*unknown* \$pattern, [*unknown* \$paths])

Adds a route to the router that only match if the HTTP method is DELETE

public Phalcon\Mvc\Router\Route addOptions (*unknown* \$pattern, [*unknown* \$paths])

Add a route to the router that only match if the HTTP method is OPTIONS

public Phalcon\Mvc\Router\Route addHead (*unknown* \$pattern, [*unknown* \$paths])

Adds a route to the router that only match if the HTTP method is HEAD

public clear ()

Removes all the pre-defined routes

2.58.193 Class Phalcon\Mvc\Router\Route

implements Phalcon\Mvc\Router\RouteInterface

This class represents every route added to the router

Methods

public __construct (*unknown* \$pattern, [*unknown* \$paths], [*unknown* \$httpMethods])

Phalcon\Mvc\Router\Route constructor

public string compilePattern (*unknown* \$pattern)

Replaces placeholders from pattern returning a valid PCRE regular expression

public Phalcon\Mvc\Router\Route via (*unknown* \$httpMethods)

Set one or more HTTP methods that constraint the matching of the route

```
<?php
```

```
$route->via('GET');
$route->via(array('GET', 'POST'));
```

public *array|boolean* **extractNamedParams** (*unknown* \$pattern)

Extracts parameters from a string

public **reConfigure** (*unknown* \$pattern, [*unknown* \$paths])

Reconfigure the route adding a new pattern and a set of paths

public *string* **getName** ()

Returns the route's name

public [Phalcon\Mvc\Router\Route](#) **setName** (*unknown* \$name)

Sets the route's name

```
<?php
```

```
$router->add('/about', array(
    'controller' => 'about'
))->setName('about');
```

public [Phalcon\Mvc\Router\Route](#) **beforeMatch** (*unknown* \$callback)

Sets a callback that is called if the route is matched. The developer can implement any arbitrary conditions here If the callback returns false the route is treated as not matched

public *mixed* **getBeforeMatch** ()

Returns the 'before match' callback if any

public *string* **getRouteId** ()

Returns the route's id

public *string* **getPattern** ()

Returns the route's pattern

public *string* **getCompiledPattern** ()

Returns the route's compiled pattern

public *array* **getPaths** ()

Returns the paths

public *array* **getReversedPaths** ()

Returns the paths using positions as keys and names as values

public [Phalcon\Mvc\Router\Route](#) **setHttpMethods** (*unknown* \$httpMethods)

Sets a set of HTTP methods that constraint the matching of the route (alias of via)

```
<?php
```

```
$route->setHttpMethods('GET');
$route->setHttpMethods(array('GET', 'POST'));
```

public *string|array* **getHttpMethods** ()

Returns the HTTP methods that constraint matching the route

public [Phalcon\Mvc\Router\Route](#) **setHostname** (*unknown* \$hostname)

Sets a hostname restriction to the route

```
<?php
$route->setHostname('localhost');

public string getHostname()
Returns the hostname restriction if any

public Phalcon\Mvc\RouteInterface setGroup (unknown $group)
Sets the group associated with the route

public Phalcon\Mvc\Router\Group |null getGroup ()
Returns the group associated with the route

public Phalcon\Mvc\Router\Route convert (unknown $name, unknown $converter)
Adds a converter to perform an additional transformation for certain parameter

public array getConverters ()
Returns the router converter

public static reset ()
Resets the internal route id generator
```

2.58.194 Class Phalcon\Mvc\Url

implements Phalcon\Mvc\UrlInterface, Phalcon\Di\InjectionAwareInterface

This components aids in the generation of: URIs, URLs and Paths

```
<?php

//Generate a URL appending the URI to the base URI
echo $url->get('products/edit/1');

//Generate a URL for a predefined route
echo $url->get(array('for' => 'blog-post', 'title' => 'some-cool-stuff', 'year' => '2012'));
```

Methods

```
public setDI (unknown $dependencyInjector)
Sets the DependencyInjector container

public Phalcon\DiInterface getDI ()
Returns the DependencyInjector container

public Phalcon\Mvc\Url setBaseUri (unknown $baseUri)
Sets a prefix for all the URIs to be generated
```

```
<?php
$url->setBaseUri('/invo/');
$url->setBaseUri('/invo/index.php');
```

public `Phalcon\Mvc\Url` **setStaticBaseUri** (*unknown* \$staticBaseUri)

Sets a prefix for all static URLs generated

```
<?php  
  
$url->setStaticBaseUri('/invo/');
```

public *string* **getBaseUri** ()

Returns the prefix for all the generated urls. By default /

public *string* **getStaticBaseUri** ()

Returns the prefix for all the generated static urls. By default /

public `Phalcon\Mvc\Url` **setbasePath** (*unknown* \$basePath)

Sets a base path for all the generated paths

```
<?php  
  
$url->setbasePath('/var/www/htdocs/');
```

public *string* **getbasePath** ()

Returns the base path

public *string* **get** ([*unknown* \$uri], [*unknown* \$args], [*bool* \$local])

Generates a URL

```
<?php  
  
//Generate a URL appending the URI to the base URI  
echo $url->get('products/edit/1');  
  
//Generate a URL for a predefined route  
echo $url->get(array('for' => 'blog-post', 'title' => 'some-cool-stuff', 'year' => '2012'));
```

public *string* **getStatic** ([*unknown* \$uri])

Generates a URL for a static resource

public *string* **path** ([*unknown* \$path])

Generates a local path

2.58.195 Class Phalcon\Mvc\Url\Exception

extends class `Phalcon\Exception`

Methods

final private *Exception* **__clone** () inherited from `Exception`

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from `Exception`

Exception constructor

final public *string* **getMessage** () inherited from `Exception`

Gets the Exception message

`final public int getCode ()` inherited from `Exception`

Gets the Exception code

`final public string getFile ()` inherited from `Exception`

Gets the file in which the exception occurred

`final public int getLine ()` inherited from `Exception`

Gets the line in which the exception occurred

`final public array getTrace ()` inherited from `Exception`

Gets the stack trace

`final public Exception getPrevious ()` inherited from `Exception`

Returns previous Exception

`final public Exception getTraceAsString ()` inherited from `Exception`

Gets the stack trace as a string

`public string __toString ()` inherited from `Exception`

String representation of the exception

2.58.196 Class Phalcon\Mvc\User\Component

extends abstract class Phalcon\Di\Injectable

implements Phalcon\Events\EventsAwareInterface, Phalcon\Di\InjectionAwareInterface

Methods

`public setDI (unknown $dependencyInjector)` inherited from `Phalcon\Di\Injectable`

Sets the dependency injector

`public Phalcon\DiInterface getDI ()` inherited from `Phalcon\Di\Injectable`

Returns the internal dependency injector

`public setEventsManager (unknown $eventsManager)` inherited from `Phalcon\Di\Injectable`

Sets the event manager

`public Phalcon\Events\ManagerInterface getEventsManager ()` inherited from `Phalcon\Di\Injectable`

Returns the internal event manager

`public __get (unknown $propertyName)` inherited from `Phalcon\Di\Injectable`

Magic method `__get`

2.58.197 Class Phalcon\Mvc\User\Module

extends abstract class Phalcon\Di\Injectable

implements Phalcon\Events\EventsAwareInterface, Phalcon\Di\InjectionAwareInterface

Methods

public **setDI** (*unknown* \$dependencyInjector) inherited from Phalcon\Di\Injectable

Sets the dependency injector

public [Phalcon\DiInterface](#) **getDI** () inherited from Phalcon\Di\Injectable

Returns the internal dependency injector

public **setEventsManager** (*unknown* \$eventsManager) inherited from Phalcon\Di\Injectable

Sets the event manager

public [Phalcon\Events\ManagerInterface](#) **getEventsManager** () inherited from Phalcon\Di\Injectable

Returns the internal event manager

public **__get** (*unknown* \$propertyName) inherited from Phalcon\Di\Injectable

Magic method __get

2.58.198 Class Phalcon\Mvc\User\Plugin

extends abstract class Phalcon\Di\Injectable

implements [Phalcon\Events\EventsAwareInterface](#), [Phalcon\Di\InjectionAwareInterface](#)

Methods

public **setDI** (*unknown* \$dependencyInjector) inherited from Phalcon\Di\Injectable

Sets the dependency injector

public [Phalcon\DiInterface](#) **getDI** () inherited from Phalcon\Di\Injectable

Returns the internal dependency injector

public **setEventsManager** (*unknown* \$eventsManager) inherited from Phalcon\Di\Injectable

Sets the event manager

public [Phalcon\Events\ManagerInterface](#) **getEventsManager** () inherited from Phalcon\Di\Injectable

Returns the internal event manager

public **__get** (*unknown* \$propertyName) inherited from Phalcon\Di\Injectable

Magic method __get

2.58.199 Class Phalcon\Mvc\View

extends abstract class Phalcon\Di\Injectable

implements [Phalcon\Events\EventsAwareInterface](#), [Phalcon\Di\InjectionAwareInterface](#), [Phalcon\Mvc\ViewInterface](#)

Phalcon\Mvc\View is a class for working with the “view” portion of the model-view-controller pattern. That is, it exists to help keep the view script separate from the model and controller scripts. It provides a system of helpers, output filters, and variable escaping.

```
<?php

//Setting views directory
$view = new \Phalcon\Mvc\View();
$view->setViewsDir('app/views/');

$view->start();
//Shows recent posts view (app/views/posts/recent.phtml)
$view->render('posts', 'recent');
$view->finish();

//Printing views output
echo $view->getContent();
```

Constants

integer **LEVEL_MAIN_LAYOUT**
integer **LEVEL_AFTER_TEMPLATE**
integer **LEVEL_LAYOUT**
integer **LEVEL_BEFORE_TEMPLATE**
integer **LEVEL_ACTION_VIEW**
integer **LEVEL_NO_RENDER**
integer **CACHE_MODE_NONE**
integer **CACHE_MODE_INVERSE**

Methods

public getRenderLevel ()
...
public getCurrentRenderLevel ()
...
public getRegisteredEngines ()
...

public __construct ([*unknown* \$options])

Phalcon\Mvc\View constructor

public Phalcon\Mvc\View setViewsDir (*unknown* \$viewsDir)

Sets the views directory. Depending of your platform, always add a trailing slash or backslash

public string getViewsDir ()

Gets views directory

public Phalcon\Mvc\View setLayoutsDir (*unknown* \$layoutsDir)

Sets the layouts sub-directory. Must be a directory under the views directory. Depending of your platform, always add a trailing slash or backslash

```
<?php  
    $view->setLayoutsDir('..../common/layouts/');
```

public string getLayoutsDir ()

Gets the current layouts sub-directory

public Phalcon\Mvc\View setPartialsDir (unknown \$partialsDir)

Sets a partials sub-directory. Must be a directory under the views directory. Depending of your platform, always add a trailing slash or backslash

```
<?php  
    $view->setPartialsDir('..../common/partials/');
```

public string getPartialsDir ()

Gets the current partials sub-directory

public Phalcon\Mvc\View setbasePath (unknown \$basePath)

Sets base path. Depending of your platform, always add a trailing slash or backslash

```
<?php  
    $view->setbasePath(__DIR__ . '/');
```

public Phalcon\Mvc\View setRenderLevel (unknown \$level)

Sets the render level for the view

```
<?php  
    //Render the view related to the controller only  
    $this->view->setRenderLevel(View::LEVEL_VIEW);
```

public Phalcon\Mvc\View disableLevel (unknown \$level)

Disables a specific level of rendering

```
<?php  
    //Render all levels except ACTION level  
    $this->view->disableLevel(View::LEVEL_ACTION_VIEW);
```

public Phalcon\Mvc\View setMainView (unknown \$viewPath)

Sets default view name. Must be a file without extension in the views directory

```
<?php  
    //Renders as main view views-dir/base.phtml  
    $this->view->setMainView('base');
```

public string getMainView ()

Returns the name of the main view

public Phalcon\Mvc\View setLayout (unknown \$layout)

Change the layout to be used instead of using the name of the latest controller name

```
<?php
    $this->view->setLayout ('main');
```

public string getLayout ()

Returns the name of the main view

public Phalcon\Mvc\View setTemplateBefore (unknown \$templateBefore)

Sets a template before the controller layout

public Phalcon\Mvc\View cleanTemplateBefore ()

Resets any “template before” layouts

public Phalcon\Mvc\View setTemplateAfter (unknown \$templateAfter)

Sets a “template after” controller layout

public Phalcon\Mvc\View cleanTemplateAfter ()

Resets any template before layouts

public Phalcon\Mvc\View setParamToView (unknown \$key, unknown \$value)

Adds parameters to views (alias of setVar)

```
<?php
    $this->view->setParamToView ('products', $products);
```

public Phalcon\Mvc\View setVars (unknown \$params, [unknown \$merge])

Set all the render params

```
<?php
    $this->view->setVars (array ('products' => $products));
```

public Phalcon\Mvc\View setVar (unknown \$key, unknown \$value)

Set a single view parameter

```
<?php
    $this->view->setVar ('products', $products);
```

public mixed getVar (unknown \$key)

Returns a parameter previously set in the view

public array getParamsToView ()

Returns parameters to views

public string getControllerName ()

Gets the name of the controller rendered

public string getActionName ()

Gets the name of the action rendered

public array getParams ()

Gets extra parameters of the action rendered

public `Phalcon\Mvc\View` **start** ()

Starts rendering process enabling the output buffering

protected `array` **_loadTemplateEngines** ()

Loads registered template engines, if none is registered it will use `Phalcon\Mvc\View\Engine\Php`

protected **_engineRender** (*unknown* \$engines, *unknown* \$viewPath, *unknown* \$silence, *unknown* \$mustClean, [`Phalcon\Cache\BackendInterface` \$cache])

Checks whether view exists on registered extensions and render it

public `Phalcon\Mvc\View` **registerEngines** (*unknown* \$engines)

Register templating engines

```
<?php

$this->view->registerEngines (array(
    ".phtml" => "Phalcon\Mvc\View\Engine\Php",
    ".volt"   => "Phalcon\Mvc\View\Engine\Volt",
    ".mhtml"  => "MyCustomEngine"
)) ;
```

public *boolean* **exists** (*unknown* \$view)

Checks whether view exists

public `Phalcon\Mvc\View` **render** (*unknown* \$controllerName, *unknown* \$actionName, [*unknown* \$params])

Executes render process from dispatching data

```
<?php

//Shows recent posts view (app/views/posts/recent.phtml)
$view->start()->render('posts', 'recent')->finish();
```

public `Phalcon\Mvc\View` **pick** (*unknown* \$renderView)

Choose a different view to render instead of last-controller/last-action

```
<?php

class ProductsController extends \Phalcon\Mvc\Controller
{

    public function saveAction()
    {

        //Do some save stuff...

        //Then show the list view
        $this->view->pick("products/list");
    }
}
```

public *string* **getPartial** (*unknown* \$partialPath, [*unknown* \$params])

Renders a partial view

```
<?php
```

```
//Retrieve the contents of a partial
echo $this->getPartial('shared/footer');
```

```
<?php

//Retrieve the contents of a partial with arguments
echo $this->getPartial('shared/footer', array('content' => $html));
```

public `partial` (*unknown* \$partialPath, [*unknown* \$params])

Renders a partial view

```
<?php

//Show a partial inside another view
$this->partial('shared/footer');
```

```
<?php

//Show a partial inside another view with parameters
$this->partial('shared/footer', array('content' => $html));
```

public `string getRender` (*unknown* \$controllerName, *unknown* \$actionName, [*unknown* \$params], [*unknown* \$configCallback])

Perform the automatic rendering returning the output as a string

```
<?php

$template = $this->view->getRender('products', 'show', array('products' => $products));
```

public `Phalcon\Mvc\View finish` ()

Finishes the render process by stopping the output buffering

protected `Phalcon\Cache\BackendInterface _createCache` ()

Create a Phalcon\Cache based on the internal cache options

public `boolean isCaching` ()

Check if the component is currently caching the output content

public `Phalcon\Cache\BackendInterface getCache` ()

Returns the cache instance used to cache

public `Phalcon\Mvc\View cache` ([*unknown* \$options])

Cache the actual view render to certain level

```
<?php

$this->view->cache(array('key' => 'my-key', 'lifetime' => 86400));
```

public `Phalcon\Mvc\View setContent` (*unknown* \$content)

Externally sets the view content

```
<?php

$this->view->setContent("<h1>hello</h1>");
```

`public string getContent ()`

Returns cached output from another view stage

`public string getActiveRenderPath ()`

Returns the path of the view that is currently rendered

`public Phalcon\Mvc\View disable ()`

Disables the auto-rendering process

`public Phalcon\Mvc\View enable ()`

Enables the auto-rendering process

`public Phalcon\Mvc\View reset ()`

Resets the view component to its factory default values

`public __set (unknown $key, unknown $value)`

Magic method to pass variables to the views

```
<?php
```

```
$this->view->products = $products;
```

`public mixed __get (unknown $key)`

Magic method to retrieve a variable passed to the view

```
<?php
```

```
echo $this->view->products;
```

`public boolean isDisabled ()`

Whether automatic rendering is enabled

`public setDI (unknown $dependencyInjector)` inherited from Phalcon\Di\Injectable

Sets the dependency injector

`public Phalcon\DiInterface getDI ()` inherited from Phalcon\Di\Injectable

Returns the internal dependency injector

`public setEventsManager (unknown $eventsManager)` inherited from Phalcon\Di\Injectable

Sets the event manager

`public Phalcon\Events\ManagerInterface getEventsManager ()` inherited from Phalcon\Di\Injectable

Returns the internal event manager

2.58.200 Abstract class Phalcon\Mvc\View\Engine

`extends abstract class Phalcon\Di\Injectable`

`implements Phalcon\Events\EventsAwareInterface, Phalcon\Di\InjectionAwareInterface`

All the template engine adapters must inherit this class. This provides basic interfacing between the engine and the Phalcon\Mvc\View component.

Methods

```
public __construct (unknown $view, [unknown $dependencyInjector])  
Phalcon\Mvc\View\Engine constructor  
public string getContent ()  
Returns cached output on another view stage  
public string partial (unknown $partialPath, [unknown $params])  
Renders a partial inside another view  
public Phalcon\Mvc\ViewInterface getView ()  
Returns the view component related to the adapter  
public setDI (unknown $dependencyInjector) inherited from Phalcon\Di\Injectable  
Sets the dependency injector  
public Phalcon\DiInterface getDI () inherited from Phalcon\Di\Injectable  
Returns the internal dependency injector  
public setEventsManager (unknown $eventsManager) inherited from Phalcon\Di\Injectable  
Sets the event manager  
public Phalcon\Events\ManagerInterface getEventsManager () inherited from Phalcon\Di\Injectable  
Returns the internal event manager  
public __get (unknown $propertyName) inherited from Phalcon\Di\Injectable  
Magic method __get
```

2.58.201 Class Phalcon\Mvc\View\Engine\Php

extends abstract class Phalcon\Mvc\View\Engine
implements Phalcon\Di\InjectionAwareInterface, Phalcon\Events\EventsAwareInterface, Phalcon\Mvc\View\EngineInterface
Adapter to use PHP itself as templating engine

Methods

```
public render (unknown $path, unknown $params, [unknown $mustClean])  
Renders a view using the template engine  
public __construct (unknown $view, [unknown $dependencyInjector]) inherited from Phalcon\Mvc\View\Engine  
Phalcon\Mvc\View\Engine constructor  
public string getContent () inherited from Phalcon\Mvc\View\Engine  
Returns cached output on another view stage  
public string partial (unknown $partialPath, [unknown $params]) inherited from Phalcon\Mvc\View\Engine  
Renders a partial inside another view  
public Phalcon\Mvc\ViewInterface getView () inherited from Phalcon\Mvc\View\Engine
```

Returns the view component related to the adapter

public **setDI** (*unknown* \$dependencyInjector) inherited from Phalcon\Di\Injectable

Sets the dependency injector

public [Phalcon\DiInterface](#) **getDI** () inherited from Phalcon\Di\Injectable

Returns the internal dependency injector

public **setEventsManager** (*unknown* \$eventsManager) inherited from Phalcon\Di\Injectable

Sets the event manager

public [Phalcon\Events\ManagerInterface](#) **getEventsManager** () inherited from Phalcon\Di\Injectable

Returns the internal event manager

public **__get** (*unknown* \$propertyName) inherited from Phalcon\Di\Injectable

Magic method __get

2.58.202 Class Phalcon\Mvc\View\Engine\Volt

extends abstract class [Phalcon\Mvc\View\Engine](#)

implements [Phalcon\Di\InjectionAwareInterface](#), [Phalcon\Events\EventsAwareInterface](#), [Phalcon\Mvc\View\EngineInterface](#)

Designer friendly and fast template engine for PHP written in C

Methods

public **setOptions** (*unknown* \$options)

Set Volt's options

public *array* **getOptions** ()

Return Volt's options

public [Phalcon\Mvc\View\Engine\Volt\Compiler](#) **getCompiler** ()

Returns the Volt's compiler

public **render** (*string* \$templatePath, *array* \$params, [*boolean* \$mustClean])

Renders a view using the template engine

public *int* **length** (*mixed* \$item)

Length filter. If an array/object is passed a count is performed otherwise a strlen(mb_strlen

public *boolean* **isIncluded** (*unknown* \$needle, *unknown* \$haystack)

Checks if the needle is included in the haystack

public *string* **convertEncoding** (*unknown* \$text, *unknown* \$from, *unknown* \$to)

Performs a string conversion

public **slice** (*unknown* \$value, *unknown* \$start, [*unknown* \$end])

Extracts a slice from a string/array/traversable object value

public *array* **sort** (*unknown* \$value)

Sorts an array

`public __construct (unknown $view, [unknown $dependencyInjector])` inherited from Phalcon\Mvc\View\Engine
Phalcon\Mvc\View\Engine constructor

`public string getContent ()` inherited from Phalcon\Mvc\View\Engine

Returns cached output on another view stage

`public string partial (unknown $partialPath, [unknown $params])` inherited from Phalcon\Mvc\View\Engine

Renders a partial inside another view

`public Phalcon\Mvc\ViewInterface getView ()` inherited from Phalcon\Mvc\View\Engine

Returns the view component related to the adapter

`public setDI (unknown $dependencyInjector)` inherited from Phalcon\Di\Injectable

Sets the dependency injector

`public Phalcon\DiInterface getDI ()` inherited from Phalcon\Di\Injectable

Returns the internal dependency injector

`public setEventsManager (unknown $eventsManager)` inherited from Phalcon\Di\Injectable

Sets the event manager

`public Phalcon\Events\ManagerInterface getEventsManager ()` inherited from Phalcon\Di\Injectable

Returns the internal event manager

`public __get (unknown $propertyName)` inherited from Phalcon\Di\Injectable

Magic method `__get`

2.58.203 Class Phalcon\Mvc\View\Engine\Volt\Compiler

implements Phalcon\Di\InjectionAwareInterface

This class reads and compiles Volt templates into PHP plain code

```
<?php

$compiler = new \Phalcon\Mvc\View\Engine\Volt\Compiler();

$compiler->compile('views/partials/header.volt');

require $compiler->getCompiledTemplatePath();
```

Methods

`public __construct ([unknown $view])`

`public setDI (unknown $dependencyInjector)`

Sets the dependency injector

`public Phalcon\DiInterface getDI ()`

Returns the internal dependency injector

`public setOptions (unknown $options)`

Sets the compiler options

public **setOption** (*unknown* \$option, *unknown* \$value)

Sets a single compiler option

public *string* **getOption** (*unknown* \$option)

Returns a compiler's option

public *array* **getOptions** ()

Returns the compiler options

final public *mixed* **fireExtensionEvent** (*unknown* \$name, [*unknown* \$arguments])

Fires an event to registered extensions

public **Phalcon\Mvc\View\Engine\Volt\Compiler addExtension** (*unknown* \$extension)

Registers a Volt's extension

public *array* **getExtensions** ()

Returns the list of extensions registered in Volt

public **Phalcon\Mvc\View\Engine\Volt\Compiler addFunction** (*unknown* \$name, *unknown* \$definition)

Register a new function in the compiler

public *array* **getFunctions** ()

Register the user registered functions

public **Phalcon\Mvc\View\Engine\Volt\Compiler addFilter** (*unknown* \$name, *unknown* \$definition)

Register a new filter in the compiler

public *array* **getFilters** ()

Register the user registered filters

public **Phalcon\Mvc\View\Engine\Volt\Compiler setUniquePrefix** (*unknown* \$prefix)

Set a unique prefix to be used as prefix for compiled variables

public *string* **getUniquePrefix** ()

Return a unique prefix to be used as prefix for compiled variables and contexts

public *string* **attributeReader** (*unknown* \$expr)

Resolves attribute reading

public *string* **functionCall** (*unknown* \$expr)

Resolves function intermediate code into PHP function calls

public *string* **resolveTest** (*unknown* \$test, *unknown* \$left)

Resolves filter intermediate code into a valid PHP expression

final protected *string* **resolveFilter** (*unknown* \$filter, *unknown* \$left)

Resolves filter intermediate code into PHP function calls

final public *string* **expression** (*unknown* \$expr)

Resolves an expression node in an AST volt tree

final protected *string|array* **_statementListOrExtends** (*unknown* \$statements)

Compiles a block of statements

`public string compileForeach (unknown $statement, [unknown $extendsMode])`

Compiles a “foreach” intermediate code representation into plain PHP code

`public string compileForElse ()`

Generates a ‘forelse’ PHP code

`public string compileIf (unknown $statement, [unknown $extendsMode])`

Compiles a ‘if’ statement returning PHP code

`public string compileElseIf (unknown $statement)`

Compiles a “elseif” statement returning PHP code

`public string compileCache (unknown $statement, [unknown $extendsMode])`

Compiles a “cache” statement returning PHP code

`public string compileSet (unknown $statement)`

Compiles a “set” statement returning PHP code

`public string compileDo (unknown $statement)`

Compiles a “do” statement returning PHP code

`public string compileReturn (unknown $statement)`

Compiles a “return” statement returning PHP code

`public string compileAutoEscape (unknown $statement, unknown $extendsMode)`

Compiles a “autoescape” statement returning PHP code

`public string compileEcho (unknown $statement)`

Compiles a ‘{{‘ ‘}}’ statement returning PHP code

`public string compileInclude (unknown $statement)`

Compiles a ‘include’ statement returning PHP code

`public string compileMacro (unknown $statement, unknown $extendsMode)`

Compiles macros

`public string compileCall (unknown $statement, unknown $extendsMode)`

Compiles calls to macros

`final protected string _statementList (unknown $statements, [unknown $extendsMode])`

Traverses a statement list compiling each of its nodes

`protected string _compileSource (unknown $viewCode, [unknown $extendsMode])`

Compiles a Volt source code returning a PHP plain version

`public string compileString (unknown $viewCode, [unknown $extendsMode])`

Compiles a template into a string

```
<?php
echo $compiler->compileString('{{ "hello world" }}');
```

public *string* **array compileFile** (*unknown* \$path, *unknown* \$compiledPath, [*unknown* \$extendsMode])

Compiles a template into a file forcing the destination path

```
<?php
```

```
$compiler->compile('views/layouts/main.volt', 'views/layouts/main.volt.php');
```

public *string* **array compile** (*unknown* \$templatePath, [*unknown* \$extendsMode])

Compiles a template into a file applying the compiler options This method does not return the compiled path if the template was not compiled

```
<?php
```

```
$compiler->compile('views/layouts/main.volt');
require $compiler->getCompiledTemplatePath();
```

public *string* **getTemplatePath** ()

Returns the path that is currently being compiled

public *string* **getCompiledTemplatePath** ()

Returns the path to the last compiled template

public *array* **parse** (*unknown* \$viewCode)

Parses a Volt template returning its intermediate representation

```
<?php
```

```
print_r($compiler->parse('{{ 3 + 2 }}'));
```

2.58.204 Class Phalcon\Mvc\View\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception
Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception
Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception
Gets the stack trace as a string

public *string* **__toString** () inherited from Exception
String representation of the exception

2.58.205 Class Phalcon\Mvc\View\Simple

extends abstract class Phalcon\Di\Injectable
implements Phalcon\Events\EventsAwareInterface, Phalcon\Di\InjectionAwareInterface
This component allows to render views without hicherquical levels

```
<?php

$view = new \Phalcon\Mvc\View\Simple();
echo $view->render('templates/my-view', array('content' => $html));
//or with filename with extension
echo $view->render('templates/my-view.volt', array('content' => $html));
```

Methods

public **getRegisteredEngines** ()
...
public **__construct** ([*unknown* \$options])
Phalcon\Mvc\View\Simple constructor
public **setViewsDir** (*unknown* \$viewsDir)
Sets views directory. Depending of your platform, always add a trailing slash or backslash
public *string* **getViewsDir** ()
Gets views directory
public **registerEngines** (*unknown* \$engines)
Register templating engines

```
<?php

$this->view->registerEngines(array(
    ".phtml" => "Phalcon\Mvc\View\Engine\Php",
    ".volt" => "Phalcon\Mvc\View\Engine\Volt",
    ".mhtml" => "MyCustomEngine"
));
```

protected array **_loadTemplateEngines** ()

Loads registered template engines, if none is registered it will use Phalcon\Mvc\View\Engine\Php

final protected **_internalRender** (*unknown* \$path, *unknown* \$params)

Tries to render the view with every engine registered in the component

public **string render** (*unknown* \$path, [*unknown* \$params])

Renders a view

public **partial** (*unknown* \$partialPath, [*unknown* \$params])

Renders a partial view

```
<?php
```

```
//Show a partial inside another view
$this->partial('shared/footer');
```

```
<?php
```

```
//Show a partial inside another view with parameters
$this->partial('shared/footer', array('content' => $html));
```

public Phalcon\Mvc\View\Simple **setCacheOptions** (*unknown* \$options)

Sets the cache options

public array **getCacheOptions** ()

Returns the cache options

protected Phalcon\Cache\BackendInterface **_createCache** ()

Create a Phalcon\Cache based on the internal cache options

public Phalcon\Cache\BackendInterface **getCache** ()

Returns the cache instance used to cache

public Phalcon\Mvc\View\Simple **cache** ([*unknown* \$options])

Cache the actual view render to certain level

```
<?php
```

```
$this->view->cache(array('key' => 'my-key', 'lifetime' => 86400));
```

public Phalcon\Mvc\View\Simple **setParamToView** (*string* \$key, *mixed* \$value)

Adds parameters to views (alias of setVar)

```
<?php
```

```
$this->view->setParamToView('products', $products);
```

public Phalcon\Mvc\View\Simple **setVars** (*unknown* \$params, [*unknown* \$merge])

Set all the render params

```
<?php
```

```
$this->view->setVars(array('products' => $products));
```

public Phalcon\Mvc\View\Simple `setVar` (*unknown* \$key, *unknown* \$value)

Set a single view parameter

```
<?php
$this->view->setVar('products', $products);
```

public mixed `getVar` (*unknown* \$key)

Returns a parameter previously set in the view

public array `getParamsToView` ()

Returns parameters to views

public Phalcon\Mvc\View\Simple `setContent` (*unknown* \$content)

Externally sets the view content

```
<?php
$this->view->setContent("<h1>hello</h1>");
```

public string `getContent` ()

Returns cached output from another view stage

public string `getActiveRenderPath` ()

Returns the path of the view that is currently rendered

public __set (*unknown* \$key, *unknown* \$value)

Magic method to pass variables to the views

```
<?php
$this->view->products = $products;
```

public mixed __get (*unknown* \$key)

Magic method to retrieve a variable passed to the view

```
<?php
echo $this->view->products;
```

public `setDI` (*unknown* \$dependencyInjector) inherited from Phalcon\Di\Injectable

Sets the dependency injector

public Phalcon\DiInterface `getDI` () inherited from Phalcon\Di\Injectable

Returns the internal dependency injector

public `setEventsManager` (*unknown* \$eventsManager) inherited from Phalcon\Di\Injectable

Sets the event manager

public Phalcon\Events\ManagerInterface `getEventsManager` () inherited from Phalcon\Di\Injectable

Returns the internal event manager

2.58.206 Class Phalcon\\Paginator\\Adapter\\Model

implements Phalcon\\Paginator\\AdapterInterface

This adapter allows to paginate data using a Phalcon\\Mvc\\Model resultset as base

Methods

public __construct (unknown \$config)

Phalcon\\Paginator\\Adapter\\Model constructor

public setcurrentPage (unknown \$page)

Set the current page number

public setLimit (unknown \$limitRows)

Set current rows limit

public getLimit ()

Get current rows limit

public getPagine ()

Returns a slice of the resultset to show in the pagination

2.58.207 Class Phalcon\\Paginator\\Adapter\\NativeArray

implements Phalcon\\Paginator\\AdapterInterface

Pagination using a PHP array as source of data

```
<?php

$paginator = new \Phalcon\\Paginator\\Adapter\\Model(
    array(
        "data"  => array(
            array('id' => 1, 'name' => 'Artichoke'),
            array('id' => 2, 'name' => 'Carrots'),
            array('id' => 3, 'name' => 'Beet'),
            array('id' => 4, 'name' => 'Lettuce'),
            array('id' => 5, 'name' => '')
        ),
        "limit" => 2,
        "page"  => $currentPage
    )
);
```

Methods

public __construct (unknown \$config)

Phalcon\\Paginator\\Adapter\\NativeArray constructor

public setcurrentPage (unknown \$page)

Set the current page number

public `setLimit` (*unknown* \$limitRows)

Set current rows limit

public `getLimit` ()

Get current rows limit

public `getPaginate` ()

Returns a slice of the resultset to show in the pagination

2.58.208 Class Phalcon\Paginator\Adapter\QueryBuilder

implements [Phalcon\Paginator\AdapterInterface](#)

Pagination using a PHQL query builder as source of data

```
<?php

$builder = $this->modelsManager->createBuilder()
    ->columns('id, name')
    ->from('Robots')
    ->orderBy('name');

$paginator = new Phalcon\Paginator\Adapter\QueryBuilder(array(
    "builder" => $builder,
    "limit"=> 20,
    "page" => 1
));
```

Methods

public `__construct` (*unknown* \$config)

public `setCurrentPage` (*unknown* \$currentPage)

Set the current page number

public `int page getCurrentPage` ()

Get the current page number

public `setLimit` (*unknown* \$limitRows)

Set current rows limit

public `getLimit` ()

Get current rows limit

public `setQueryBuilder` (*unknown* \$builder)

Set query builder object

public `getQueryBuilder` ()

Get query builder object

public `getPaginate` ()

Returns a slice of the resultset to show in the pagination

2.58.209 Class Phalcon\Paginator\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception

Gets the stack trace as a string

public *string* **__toString** () inherited from Exception

String representation of the exception

2.58.210 Class Phalcon\Queue\Beanstalk

- Phalcon\Queue\Beanstalk * * Class to access the beanstalk queue service. * Partially implements the protocol version 1.2 *

Methods

public **__construct** ([*unknown* \$options])

public *resource* **connect** ()

Makes a connection to the Beanstalkd server

public **put** (*unknown* \$data, [*unknown* \$options])

Inserts jobs into the queue

public *boolean|Phalcon\Queue\BeanstalkJob* **reserve** ([*unknown* \$timeout])

Reserves a job in the queue

`public string|boolean choose (unknown $tube)`

Change the active tube. By default the tube is “default”

`public string|boolean watch (unknown $tube)`

Change the active tube. By default the tube is “default”

`public boolean|Phalcon\Queue\Beanstalk\Job peekReady ()`

Inspect the next ready job.

`public boolean|Phalcon\Queue\Beanstalk\Job peekBuried ()`

Return the next job in the list of buried jobs

`final public array readStatus ()`

Reads the latest status from the Beanstalkd server

`public string|boolean Data or 'false' on error: read ([unknown $length])`

Reads a packet from the socket. Prior to reading from the socket will check for availability of the connection.

`protected integer|boolean write (unknown $data)`

Writes data to the socket. Performs a connection if none is available

`public boolean disconnect ()`

Closes the connection to the beanstalk server.

2.58.211 Class Phalcon\Queue\Beanstalk\Job

- `Phalcon\Queue\Beanstalk\Job` * * Represents a job in a beanstalk queue

Methods

`public getId ()`

...

`public getBody ()`

...

`public __construct (unknown $queue, unknown $id, unknown $body)`

`public boolean delete ()`

Removes a job from the server entirely

`public boolean release ([unknown $priority], [unknown $delay])`

The release command puts a reserved job back into the ready queue (and marks its state as “ready”) to be run by any client. It is normally used when the job fails because of a transitory error.

`public boolean bury ([unknown $priority])`

The bury command puts a job into the “buried” state. Buried jobs are put into a FIFO linked list and will not be touched by the server again until a client kicks them with the “kick” command.

`public boolean touch ()`

The `touch` command allows a worker to request more time to work on a job. This is useful for jobs that potentially take a long time, but you still want the benefits of a TTR pulling a job away from an unresponsive worker. A worker may periodically tell the server that it's still alive and processing a job (e.g. it may do this on `DEADLINE_SOON`). The command postpones the auto release of a reserved job until TTR seconds from when the command is issued.

`public boolean kick ()`

Move the job to the ready queue if it is delayed or buried.

`public __wakeup ()`

...

2.58.212 Final class Phalcon\Registry

implements ArrayAccess, Countable, Iterator, Traversable

A registry is a container for storing objects and values in the application space. By storing the value in a registry, the same object is always available throughout your application.

```
<?php

$registry = new \Phalcon\Registry();

// Set value
$registry->something = 'something';
// or
$registry['something'] = 'something';

// Get value
$value = $registry->something;
// or
$value = $registry['something'];

// Check if the key exists
$exists = isset($registry->something);
// or
$exists = isset($registry['something']);

// Unset
unset($registry->something);
// or
unset($registry['something']);

In addition to ArrayAccess, Phalcon\\Registry also implements Countable (count($registry)) will return
```

Methods

`final public __construct ()`

Registry constructor

`final public offsetExists (unknown $offset)`

Checks if the element is present in the registry

`final public offsetGet (unknown $offset)`

Returns an index in the registry

final public **offsetSet** (*unknown* \$offset, *unknown* \$value)

Sets an element in the registry

final public **offsetUnset** (*unknown* \$offset)

Unsets an element in the registry

final public **__set** (*unknown* \$offset, *unknown* \$value)

Sets an element in the registry

final public **__get** (*unknown* \$offset)

Returns an index in the registry

final public **int count** ()

Checks how many elements are in the register

final public **next** ()

Moves cursor to next row in the registry

final public **int key** ()

Gets pointer number of active row in the registry

final public **rewind** ()

Rewinds the registry cursor to its beginning

public **valid** ()

Checks if the iterator is valid

public **current** ()

2.58.213 Class Phalcon\Security

implements Phalcon\Di\InjectionAwareInterface

This component provides a set of functions to improve the security in Phalcon applications

```
<?php

$login = $this->request->getPost('login');
$password = $this->request->getPost('password');

$user = Users::findFirstByLogin($login);
if ($user) {
    if ($this->security->checkHash($password, $user->password)) {
        //The password is valid
    }
}
```

Methods

public **setWorkFactor** (*unknown* \$workFactor)

...

public **getWorkFactor** ()

...

public `setDI` (`Phalcon\DiInterface` \$dependencyInjector)

Sets the dependency injector

public `getDI` ()

Returns the internal dependency injector

public `setRandomBytes` (*unknown* \$randomBytes)

Sets a number of bytes to be generated by the openssl pseudo random generator

public `getRandomBytes` ()

Returns a number of bytes to be generated by the openssl pseudo random generator

public `getSaltBytes` ()

Generate a >22-length pseudo random string to be used as salt for passwords

public `hash` (*unknown* \$password, [*unknown* \$workFactor])

Creates a password hash using bcrypt with a pseudo random salt

public `checkHash` (*unknown* \$password, *unknown* \$passwordHash, [*unknown* \$maxPassLength])

Checks a plain text password and its hash version to check if the password matches

public `isLegacyHash` (*unknown* \$password, *unknown* \$passwordHash)

Checks if a password hash is a valid bcrypt's hash

public `getTokenKey` ([*unknown* \$numberBytes])

Generates a pseudo random token key to be used as input's name in a CSRF check

public `getToken` ([*unknown* \$numberBytes])

Generates a pseudo random token value to be used as input's value in a CSRF check

public `checkToken` ([*unknown* \$tokenKey], [*unknown* \$tokenValue])

Check if the CSRF token sent in the request is the same that the current in session

public `getSessionToken` ()

Returns the value of the CSRF token in session

public `computeHmac` (*unknown* \$data, *unknown* \$key, *unknown* \$algo, [*unknown* \$raw])

`string \Phalcon\Security::computeHmac(string $data, string $key, string $algo, bool $raw = false)`

2.58.214 Class Phalcon\Security\Exception

extends class Phalcon\Exception

Methods

final private `Exception __clone` () inherited from Exception

Clone the exception

public `__construct` ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception
 Gets the Exception message

final public *int* **getCode** () inherited from Exception
 Gets the Exception code

final public *string* **getFile** () inherited from Exception
 Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception
 Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception
 Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception
 Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception
 Gets the stack trace as a string

public *string* **__toString** () inherited from Exception
 String representation of the exception

2.58.215 Abstract class Phalcon\Session

2.58.216 Abstract class Phalcon\Session\Adapter

Base class for Phalcon\Session adapters

Methods

public **__construct** ([*unknown \$options*])
 Phalcon\Session\Adapter constructor

public **boolean start** ()
 Starts the session (if headers are already sent the session will not be started)

public **setOptions** (*unknown \$options*)
 Sets session's options

```
<?php
session->setOptions (array(
    'uniqueId' => 'my-private-app'
));
```

public *array* **getOptions** ()
 Get internal options

public *mixed* **get** (*unknown \$index*, [*unknown \$defaultValue*], [*unknown \$remove*])
 Gets a session variable from an application context

public **set** (*unknown \$index, unknown \$value*)

Sets a session variable in an application context

```
<?php  
session->set ('auth', 'yes');
```

public **has** (*unknown \$index*)

Check whether a session variable is set in an application context

```
<?php  
var_dump ($session->has ('auth'));
```

public **remove** (*unknown \$index*)

Removes a session variable from an application context

```
<?php  
$session->remove ('auth');
```

public **getId** ()

Returns active session id

```
<?php  
echo $session->getId();
```

public **setId** (*unknown \$id*)

Set the current session id

```
<?php  
$session->setId($id);
```

public **isStarted** ()

Check whether the session has been started

```
<?php  
var_dump ($session->isStarted());
```

public **destroy** ()

Destroys the active session

```
<?php  
var_dump (session->destroy());
```

public *mixed __get* (*unknown \$index*)

Alias: Gets a session variable from an application context

public **__set** (*unknown \$index, unknown \$value*)

Alias: Sets a session variable in an application context

public **__isset** (*unknown \$index*)

Alias: Check whether a session variable is set in an application context

```
public __unset (unknown $index)
```

Alias: Removes a session variable from an application context

2.58.217 Class Phalcon\Session\Adapter\Files

extends abstract class `Phalcon\Session\Adapter`

implements `Phalcon\Session\AdapterInterface`

Methods

public __construct (*[unknown \$options]*) inherited from `Phalcon\Session\Adapter`

`Phalcon\Session\Adapter` constructor

public *boolean* start () inherited from `Phalcon\Session\Adapter`

Starts the session (if headers are already sent the session will not be started)

public **setOptions** (*unknown \$options*) inherited from `Phalcon\Session\Adapter`

Sets session's options

```
<?php
session->setOptions (array (
    'uniqueId' => 'my-private-app'
));
```

public *array* **getOptions** () inherited from `Phalcon\Session\Adapter`

Get internal options

public *mixed* **get** (*unknown \$index, [unknown \$defaultValue], [unknown \$remove]*) inherited from `Phalcon\Session\Adapter`

Gets a session variable from an application context

public **set** (*unknown \$index, unknown \$value*) inherited from `Phalcon\Session\Adapter`

Sets a session variable in an application context

```
<?php
session->set ('auth', 'yes');
```

public **has** (*unknown \$index*) inherited from `Phalcon\Session\Adapter`

Check whether a session variable is set in an application context

```
<?php
var_dump ($session->has ('auth'));
```

public **remove** (*unknown \$index*) inherited from `Phalcon\Session\Adapter`

Removes a session variable from an application context

```
<?php  
$session->remove('auth');
```

public **getId** () inherited from Phalcon\Session\Adapter

Returns active session id

```
<?php  
echo $session->getId();
```

public **setId** (*unknown* \$id) inherited from Phalcon\Session\Adapter

Set the current session id

```
<?php  
$session->setId($id);
```

public **isStarted** () inherited from Phalcon\Session\Adapter

Check whether the session has been started

```
<?php  
var_dump($session->isStarted());
```

public **destroy** () inherited from Phalcon\Session\Adapter

Destroys the active session

```
<?php  
var_dump(session->destroy());
```

public *mixed* **_get** (*unknown* \$index) inherited from Phalcon\Session\Adapter

Alias: Gets a session variable from an application context

public **_set** (*unknown* \$index, *unknown* \$value) inherited from Phalcon\Session\Adapter

Alias: Sets a session variable in an application context

public **_isset** (*unknown* \$index) inherited from Phalcon\Session\Adapter

Alias: Check whether a session variable is set in an application context

public **_unset** (*unknown* \$index) inherited from Phalcon\Session\Adapter

Alias: Removes a session variable from an application context

2.58.218 Class Phalcon\Session\Adapter\Libmemcached

extends abstract class Phalcon\Session\Adapter

implements Phalcon\Session\AdapterInterface

This adapter store sessions in libmemcached

```
<?php

$session = new Phalcon\Session\Adapter\Libmemcached(array(
    'servers' => array(
        array('host' => 'localhost', 'port' => 11211, 'weight' => 1),
    ),
    'client' => array(
        Memcached::OPT_HASH => Memcached::HASH_MD5,
        Memcached::OPT_PREFIX_KEY => 'prefix.',
    ),
    'lifetime' => 3600,
    'prefix' => 'my_'
));
$session->start();
$session->set('var', 'some-value');
echo $session->get('var');
```

Methods

public getLibmemcached ()

...

public getLifetime ()

...

public __construct ([*unknown* \$options])

Phalcon\Session\Adapter\Libmemcached constructor

public open ()

...

public close ()

...

public mixed read (*unknown* \$sessionId)

public write (*unknown* \$sessionId, *unknown* \$data)

public boolean destroy ([*unknown* \$session_id])

public gc ()

public boolean start () inherited from Phalcon\Session\Adapter

Starts the session (if headers are already sent the session will not be started)

public setOptions (*unknown* \$options) inherited from Phalcon\Session\Adapter

Sets session's options

```
<?php

session->setOptions(array(
    'uniqueId' => 'my-private-app'
));
```

public *array* **getOptions** () inherited from Phalcon\Session\Adapter

Get internal options

public *mixed* **get** (*unknown* \$index, [*unknown* \$defaultValue], [*unknown* \$remove]) inherited from Phalcon\Session\Adapter

Gets a session variable from an application context

public **set** (*unknown* \$index, *unknown* \$value) inherited from Phalcon\Session\Adapter

Sets a session variable in an application context

```
<?php  
session->set('auth', 'yes');
```

public **has** (*unknown* \$index) inherited from Phalcon\Session\Adapter

Check whether a session variable is set in an application context

```
<?php  
var_dump($session->has('auth'));
```

public **remove** (*unknown* \$index) inherited from Phalcon\Session\Adapter

Removes a session variable from an application context

```
<?php  
$session->remove('auth');
```

public **getId** () inherited from Phalcon\Session\Adapter

Returns active session id

```
<?php  
echo $session->getId();
```

public **setId** (*unknown* \$id) inherited from Phalcon\Session\Adapter

Set the current session id

```
<?php  
$session->setId($id);
```

public **isStarted** () inherited from Phalcon\Session\Adapter

Check whether the session has been started

```
<?php  
var_dump($session->isStarted());
```

public *mixed* **__get** (*unknown* \$index) inherited from Phalcon\Session\Adapter

Alias: Gets a session variable from an application context

public **__set** (*unknown* \$index, *unknown* \$value) inherited from Phalcon\Session\Adapter

Alias: Sets a session variable in an application context

public **__isset** (*unknown* \$index) inherited from Phalcon\Session\Adapter

Alias: Check whether a session variable is set in an application context

`public __unset (unknown $index)` inherited from Phalcon\Session\Adapter

Alias: Removes a session variable from an application context

2.58.219 Class Phalcon\Session\Adapter\Memcache

extends abstract class Phalcon\Session\Adapter

implements Phalcon\Session\AdapterInterface

This adapter store sessions in memcache

```
<?php

$session = new \Phalcon\Session\Adapter\Memcache (array (
    'uniqueId' => 'my-private-app',
    'host' => '127.0.0.1',
    'port' => 11211,
    'persistent' => TRUE,
    'lifetime' => 3600,
    'prefix' => 'my_'
));

$session->start();

$session->set ('var', 'some-value');

echo $session->get ('var');
```

Methods

`public getMemcache ()`

...

`public getLifetime ()`

...

`public __construct ([unknown $options])`

Phalcon\Session\Adapter\Memcache constructor

`public open ()`

...

`public close ()`

...

`public mixed read (unknown $sessionId)`

`public write (unknown $sessionId, unknown $data)`

`public boolean destroy ([unknown $session_id])`

`public gc ()`

`public boolean start ()` inherited from Phalcon\Session\Adapter

Starts the session (if headers are already sent the session will not be started)

public **setOptions** (*unknown \$options*) inherited from Phalcon\Session\Adapter

Sets session's options

```
<?php  
  
session->setOptions (array (  
    'uniqueId' => 'my-private-app'  
) );
```

public *array getOptions* () inherited from Phalcon\Session\Adapter

Get internal options

public *mixed get* (*unknown \$index*, [*unknown \$defaultValue*], [*unknown \$remove*]) inherited from Phalcon\Session\Adapter

Gets a session variable from an application context

public **set** (*unknown \$index*, *unknown \$value*) inherited from Phalcon\Session\Adapter

Sets a session variable in an application context

```
<?php  
  
session->set ('auth', 'yes');
```

public **has** (*unknown \$index*) inherited from Phalcon\Session\Adapter

Check whether a session variable is set in an application context

```
<?php  
  
var_dump ($session->has ('auth'));
```

public **remove** (*unknown \$index*) inherited from Phalcon\Session\Adapter

Removes a session variable from an application context

```
<?php  
  
$session->remove ('auth');
```

public **getId** () inherited from Phalcon\Session\Adapter

Returns active session id

```
<?php  
  
echo $session->getId();
```

public **setId** (*unknown \$id*) inherited from Phalcon\Session\Adapter

Set the current session id

```
<?php  
  
$session->setId ($id);
```

public **isStarted** () inherited from Phalcon\Session\Adapter

Check whether the session has been started

```
<?php
var_dump($session->isStarted());
```

public *mixed* **__get** (*unknown* \$index) inherited from Phalcon\Session\Adapter

Alias: Gets a session variable from an application context

public **__set** (*unknown* \$index, *unknown* \$value) inherited from Phalcon\Session\Adapter

Alias: Sets a session variable in an application context

public **__isset** (*unknown* \$index) inherited from Phalcon\Session\Adapter

Alias: Check whether a session variable is set in an application context

public **__unset** (*unknown* \$index) inherited from Phalcon\Session\Adapter

Alias: Removes a session variable from an application context

2.58.220 Class Phalcon\Session\Bag

implements Phalcon\Di\InjectionAwareInterface, Phalcon\Session\BagInterface

This component helps to separate session data into “namespaces”. Working by this way you can easily create groups of session variables into the application

```
<?php
$user = new \Phalcon\Session\Bag('user');
$user->name = "Kimbra Johnson";
$user->age = 22;
```

Methods

public **__construct** (*unknown* \$name)

Phalcon\Session\Bag constructor

public **setDI** (*unknown* \$dependencyInjector)

Sets the DependencyInjector container

public Phalcon\DiInterface **getDI** ()

Returns the DependencyInjector container

public **initialize** ()

Initializes the session bag. This method must not be called directly, the class calls it when its internal data is accessed

public **destroy** ()

Destroys the session bag

```
<?php
$user->destroy();
```

public **set** (*unknown* \$property, *unknown* \$value)

Sets a value in the session bag

```
<?php  
    $user->set('name', 'Kimbra');
```

public __set (unknown \$property, unknown \$value)

Magic setter to assign values to the session bag

```
<?php  
    $user->name = "Kimbra";
```

public mixed get (unknown \$property, [unknown \$defaultValue])

Obtains a value from the session bag optionally setting a default value

```
<?php  
    echo $user->get('name', 'Kimbra');
```

public mixed __get (unknown \$property)

Magic getter to obtain values from the session bag

```
<?php  
    echo $user->name;
```

public boolean has (unknown \$property)

Check whether a property is defined in the internal bag

```
<?php  
    var_dump($user->has('name'));
```

public boolean __isset (unknown \$property)

Magic isset to check whether a property is defined in the bag

```
<?php  
    var_dump(isset($user['name']));
```

public boolean remove (unknown \$property)

Removes a property from the internal bag

```
<?php  
    $user->remove('name');
```

public boolean __unset (unknown \$property)

Magic unset to remove items using the array syntax

```
<?php  
    unset($user['name']);
```

2.58.221 Class Phalcon\Session\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception

Gets the stack trace as a string

public *string* **__toString** () inherited from Exception

String representation of the exception

2.58.222 Class Phalcon\Tag

Phalcon\Tag is designed to simplify building of HTML tags. It provides a set of helpers to generate HTML in a dynamic way. This component is an abstract class that you can extend to add more helpers.

Constants

integer **HTML32**

integer **HTML401_STRICT**

integer **HTML401_TRANSITIONAL**

integer **HTML401_FRAMESET**

integer **HTML5**

integer **XHTML10_STRICT**

integer XHTML10_TRANSITIONAL

integer XHTML10_FRAMESET

integer XHTML11

integer XHTML20

integer XHTML5

Methods

public static **getEscaper** (*unknown \$params*)

Obtains the ‘escaper’ service if required

public static *string renderAttributes* (*unknown \$code, unknown \$attributes*)

Renders parameters keeping order in their HTML attributes

public static **setDI** (*unknown \$dependencyInjector*)

Sets the dependency injector container.

public static **Phalcon\DiInterface getDI** ()

Internally gets the request dispatcher

public static **Phalcon\Mvc\UrlInterface getUrlService** ()

Returns a URL service from the default DI

public static **Phalcon\EscaperInterface getEscaperService** ()

Returns an Escaper service from the default DI

public static **setAutoescape** (*unknown \$autoescape*)

Set autoescape mode in generated html

public static **setDefault** (*unknown \$id, unknown \$value*)

Assigns default values to generated tags by helpers

```
<?php

//Assigning "peter" to "name" component
Phalcon\Tag::setDefault("name", "peter");

//Later in the view
echo Phalcon\Tag::textField("name"); //Will have the value "peter" by default
```

public static **setDefaults** (*unknown \$values, [unknown \$merge]*)

Assigns default values to generated tags by helpers

```
<?php

//Assigning "peter" to "name" component
Phalcon\Tag::setDefaults(array("name" => "peter"));

//Later in the view
echo Phalcon\Tag::textField("name"); //Will have the value "peter" by default
```

public static **displayTo** (*unknown* \$id, *unknown* \$value)

Alias of Phalcon\Tag::setDefault

public static **boolean hasValue** (*unknown* \$name)

Check if a helper has a default value set using Phalcon\Tag::setDefault or value from _POST

public static **mixed getValue** (*unknown* \$name, [*unknown* \$params])

Every helper calls this function to check whether a component has a predefined value using Phalcon\Tag::setDefault or value from _POST

public static **resetInput** ()

Resets the request and internal values to avoid those fields will have any default value

public static **string linkTo** (*unknown* \$parameters, [*unknown* \$text], [*unknown* \$local])

Builds a HTML A tag using framework conventions

```
<?php

echo Phalcon\Tag::linkTo("signup/register", "Register Here!");
echo Phalcon\Tag::linkTo(array("signup/register", "Register Here!"));
echo Phalcon\Tag::linkTo(array("signup/register", "Register Here!", "class" => "btn-primary"));
echo Phalcon\Tag::linkTo("http://phalconphp.com/", "Phalcon", FALSE);
echo Phalcon\Tag::linkTo(array("http://phalconphp.com/", "Phalcon Home", FALSE));
echo Phalcon\Tag::linkTo(array("http://phalconphp.com/", "Phalcon Home", "local" =>FALSE));
```

final protected static **string _inputField** (*unknown* \$type, *unknown* \$parameters, [*unknown* \$asValue])

Builds generic INPUT tags

final protected static **string _inputFieldChecked** (*unknown* \$type, *unknown* \$parameters)

Builds INPUT tags that implements the checked attribute

public static **string colorField** (*unknown* \$parameters)

Builds a HTML input[type="color"] tag

public static **string textField** (*unknown* \$parameters)

Builds a HTML input[type="text"] tag

```
<?php
```

```
echo Phalcon\Tag::textField(array("name", "size" => 30));
```

public static **string numericField** (*unknown* \$parameters)

Builds a HTML input[type="number"] tag

```
<?php
```

```
echo Phalcon\Tag::numericField(array("price", "min" => "1", "max" => "5"));
```

public static **string rangeField** (*unknown* \$parameters)

Builds a HTML input[type="range"] tag

public static **string emailField** (*unknown* \$parameters)

Builds a HTML input[type="email"] tag

```
<?php  
  
echo Phalcon\Tag::emailField("email");
```

public static *string* **dateField** (*unknown* \$parameters)

Builds a HTML input[type="date"] tag

```
<?php  
  
echo Phalcon\Tag::dateField(array("born", "value" => "14-12-1980"))
```

public static *string* **dateTimeField** (*unknown* \$parameters)

Builds a HTML input[type="datetime"] tag

public static *string* **dateTimeLocalField** (*unknown* \$parameters)

Builds a HTML input[type="datetime-local"] tag

public static *string* **monthField** (*unknown* \$parameters)

Builds a HTML input[type="month"] tag

public static *string* **timeField** (*unknown* \$parameters)

Builds a HTML input[type="time"] tag

public static *string* **weekField** (*unknown* \$parameters)

Builds a HTML input[type="week"] tag

public static *string* **passwordField** (*unknown* \$parameters)

Builds a HTML input[type="password"] tag

```
<?php  
  
echo Phalcon\Tag::passwordField(array("name", "size" => 30));
```

public static *string* **hiddenField** (*unknown* \$parameters)

Builds a HTML input[type="hidden"] tag

```
<?php  
  
echo Phalcon\Tag::hiddenField(array("name", "value" => "mike"));
```

public static *string* **fileField** (*unknown* \$parameters)

Builds a HTML input[type="file"] tag

```
<?php  
  
echo Phalcon\Tag::fileField("file");
```

public static *string* **searchField** (*unknown* \$parameters)

Builds a HTML input[type="search"] tag

public static *string* **telField** (*unknown* \$parameters)

Builds a HTML input[type="tel"] tag

public static *string* **urlField** (*unknown* \$parameters)

Builds a HTML input[type="url"] tag

public static *string* **checkField** (*unknown* \$parameters)

Builds a HTML input[type="checkbox"] tag

```
<?php
echo Phalcon\Tag::checkField(array("terms", "value" => "Y"));
```

public static *string* **radioField** (*unknown* \$parameters)

Builds a HTML input[type="radio"] tag

```
<?php
echo Phalcon\Tag::radioField(array("weather", "value" => "hot"));
```

Volt syntax:

```
<?php
{{ radio_field("Save") }}
```

public static *string* **imageInput** (*unknown* \$parameters)

Builds a HTML input[type="image"] tag

```
<?php
echo Phalcon\Tag::imageInput(array("src" => "/img/button.png"));
```

Volt syntax:

```
<?php
{{ image_input("src": "/img/button.png") }}
```

public static *string* **submitButton** (*unknown* \$parameters)

Builds a HTML input[type="submit"] tag

```
<?php
echo Phalcon\Tag::submitButton("Save")
```

Volt syntax:

```
<?php
{{ submit_button("Save") }}
```

public static *string* **selectStatic** (*unknown* \$parameters, [*unknown* \$data])

Builds a HTML SELECT tag using a PHP array for options

```
<?php
echo Phalcon\Tag::selectStatic("status", array("A" => "Active", "I" => "Inactive"))
```

public static *string* **select** (*unknown* \$parameters, [*unknown* \$data])

Builds a HTML SELECT tag using a Phalcon\Mvc\Model resultset as options

```
<?php

echo Phalcon\Tag::select(array(
    "robotId",
    Robots::find("type = "mechanical"),
    "using" => array("id", "name")
));
```

Volt syntax:

```
<?php

{{ select("robotId", robots, "using": ["id", "name"]) }}
```

public static *string* **textArea** (*unknown* \$parameters)

Builds a HTML TEXTAREA tag

```
<?php

echo Phalcon\Tag::textArea(array("comments", "cols" => 10, "rows" => 4))
```

Volt syntax:

```
<?php

{{ text_area("comments", "cols": 10, "rows": 4) }}
```

public static *string* **form** (*unknown* \$parameters)

Builds a HTML FORM tag

```
<?php

echo Phalcon\Tag::form("posts/save");
echo Phalcon\Tag::form(array("posts/save", "method" => "post"));
```

Volt syntax:

```
<?php

{{ form("posts/save") }}
{{ form("posts/save", "method": "post") }}
```

public static *string* **endForm** ()

Builds a HTML close FORM tag

public static **setTitle** (*unknown* \$title)

Set the title of view content

```
<?php

Phalcon\Tag::setTitle("Welcome to my Page");
```

public static **setTitleSeparator** (*unknown* \$titleSeparator)

Set the title separator of view content

```
<?php

Phalcon\Tag::setTitleSeparator("-");
```

public static **appendTitle** (*unknown \$title*)

Appends a text to current document title

public static **prependTitle** (*unknown \$title*)

Prepends a text to current document title

public static *string* **getTitle** ([*unknown \$tags*])

Gets the current document title

```
<?php
echo Phalcon\Tag::getTitle();
```

```
<?php
{{ get_title() }}
```

public static *string* **getTitleSeparator** ()

Gets the current document title separator

```
<?php
echo Phalcon\Tag::getTitleSeparator();
```

```
<?php
{{ get_title_separator() }}
```

public static *string* **stylesheetLink** ([*unknown \$parameters*], [*unknown \$local*])

Builds a LINK[rel="stylesheet"] tag

```
<?php
echo Phalcon\Tag::stylesheetLink("http://fonts.googleapis.com/css?family=Rosario", false);
echo Phalcon\Tag::stylesheetLink("css/style.css");
```

Volt Syntax:

```
<?php
{{ stylesheet_link("http://fonts.googleapis.com/css?family=Rosario", false) }}
{{ stylesheet_link("css/style.css") }}
```

public static *string* **javascriptInclude** ([*unknown \$parameters*], [*unknown \$local*])

Builds a SCRIPT[type="javascript"] tag

```
<?php
echo Phalcon\Tag::javascriptInclude("http://ajax.googleapis.com/ajax/libs/jquery/1.7.1/jquery.js");
echo Phalcon\Tag::javascriptInclude("javascript/jquery.js");
```

Volt syntax:

```
<?php
{{ javascript_include("http://ajax.googleapis.com/ajax/libs/jquery/1.7.1/jquery.min.js", false) }}
{{ javascript_include("javascript/jquery.js") }}
```

public static *string* **image** ([*unknown* \$parameters], [*unknown* \$local])

Builds HTML IMG tags

```
<?php

    echo Phalcon\Tag::image("img/bg.png");
    echo Phalcon\Tag::image(array("img/photo.jpg", "alt" => "Some Photo"));
```

Volt Syntax:

```
<?php

{{ image("img/bg.png") }}
{{ image("img/photo.jpg", "alt": "Some Photo") }}
{{ image("http://static.mywebsite.com/img/bg.png", false) }}
```

public static *text* **friendlyTitle** (*unknown* \$text, [*unknown* \$separator], [*unknown* \$lowercase], [*unknown* \$replace])

Converts texts into URL-friendly titles

```
<?php

echo Phalcon\Tag::friendlyTitle("These are big important news", "-")
```

public static **setDocType** (*unknown* \$doctype)

Set the document type of content

public static *string* **getDocType** ()

Get the document type declaration of content

public static *string* **tagHtml** (*unknown* \$tagName, [*unknown* \$parameters], [*unknown* \$selfClose], [*unknown* \$onlyStart], [*unknown* \$useEol])

Builds a HTML tag

```
<?php

echo Phalcon\Tag::tagHtml(name, parameters, selfClose, onlyStart, eol);
```

public static *string* **tagHtmlClose** (*unknown* \$tagName, [*unknown* \$useEol])

Builds a HTML tag closing tag

```
<?php

echo Phalcon\Tag::tagHtmlClose("script", true)
```

2.58.223 Class Phalcon\Tag\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception

Gets the stack trace as a string

public *string* **__toString** () inherited from Exception

String representation of the exception

2.58.224 Abstract class Phalcon\Tag\Select

Generates a SELECT html tag using a static array of values or a Phalcon\Mvc\Model resultset

Methods

public static **selectField** (*unknown* \$parameters, [*unknown* \$data])

Generates a SELECT tag

private static **_optionsFromResultset** (*unknown* \$resultset, *unknown* \$using, *unknown* \$value, *unknown* \$closeOption)

Generate the OPTION tags based on a resulset

private static **_optionsFromArray** (*unknown* \$data, *unknown* \$value, *unknown* \$closeOption)

Generate the OPTION tags based on an array

2.58.225 Abstract class Phalcon\Text

Provides utilities to work with texts

Constants

integer **RANDOM_ALNUM**
integer **RANDOM_ALPHA**
integer **RANDOM_HEXDEC**
integer **RANDOM_NUMERIC**
integer **RANDOM_NOZERO**

Methods

public static *string* **camelize** (*unknown* \$str)

Converts strings to camelize style

```
<?php  
echo Phalcon\Text:::camelize('coco_bongo'); //CocoBongo
```

public static *string* **uncamelize** (*unknown* \$str)

Uncamelize strings which are camelized

```
<?php  
echo Phalcon\Text:::camelize('CocoBongo'); //coco_bongo
```

public static *string* **increment** (*string* \$str, [*string* \$separator])

Adds a number to a string or increment that number if it already is defined

```
<?php  
echo Phalcon\Text:::increment("a"); // "a_1"  
echo Phalcon\Text:::increment("a_1"); // "a_2"
```

public static *string* **random** ([*unknown* \$type], [*unknown* \$length])

Generates a random string based on the given type. Type is one of the RANDOM_* constants

```
<?php  
echo Phalcon\Text:::random(Phalcon\Text:::RANDOM_ALNUM); //"aloiwkqz"
```

public static *boolean* **startsWith** (*unknown* \$str, *unknown* \$start, [*unknown* \$ignoreCase])

Check if a string starts with a given string

```
<?php  
echo Phalcon\Text:::startsWith("Hello", "He"); // true  
echo Phalcon\Text:::startsWith("Hello", "he"); // false  
echo Phalcon\Text:::startsWith("Hello", "he", false); // true
```

public static *boolean* **endsWith** (*unknown* \$str, *unknown* \$end, [*unknown* \$ignoreCase])

Check if a string ends with a given string

```
<?php

echo Phalcon\Text::endsWith("Hello", "llo"); // true
echo Phalcon\Text::endsWith("Hello", "LLO"); // false
echo Phalcon\Text::endsWith("Hello", "LLO", false); // true
```

public static string lower (string \$str)

Lowercases a string, this function makes use of the mbstring extension if available

public static string upper (unknown \$str)

Uppercases a string, this function makes use of the mbstring extension if available

2.58.226 Abstract class Phalcon\Translate

2.58.227 Abstract class Phalcon\Translate\Adapter

Base class for Phalcon\Translate adapters

Methods

public string t (unknown \$translateKey, [unknown \$placeholders])

Returns the translation string of the given key

public string _ (unknown \$translateKey, [unknown \$placeholders])

Returns the translation string of the given key (alias of method ‘t’)

public offsetSet (unknown \$offset, unknown \$value)

Sets a translation value

public boolean offsetExists (unknown \$translateKey)

Check whether a translation key exists

public offsetUnset (unknown \$offset)

Unsets a translation from the dictionary

public string offsetGet (unknown \$translateKey)

Returns the translation related to the given key

2.58.228 Class Phalcon\Translate\Adapter\Csv

extends abstract class Phalcon\Translate\Adapter

implements Phalcon\Translate\AdapterInterface, ArrayAccess

Methods

public __construct (unknown \$options)

Phalcon\Translate\Adapter\Csv constructor

public string query (unknown \$index, [unknown \$placeholders])

Returns the translation related to the given key

`public bool exists (unknown $index)`

Check whether is defined a translation key in the internal array

`public string t (unknown $translateKey, [unknown $placeholders])` inherited from Phalcon\Translate\Adapter

Returns the translation string of the given key

`public string _ (unknown $translateKey, [unknown $placeholders])` inherited from Phalcon\Translate\Adapter

Returns the translation string of the given key (alias of method ‘t’)

`public offsetSet (unknown $offset, unknown $value)` inherited from Phalcon\Translate\Adapter

Sets a translation value

`public boolean offsetExists (unknown $translateKey)` inherited from Phalcon\Translate\Adapter

Check whether a translation key exists

`public offsetUnset (unknown $offset)` inherited from Phalcon\Translate\Adapter

Unsets a translation from the dictionary

`public string offsetGet (unknown $translateKey)` inherited from Phalcon\Translate\Adapter

Returns the translation related to the given key

2.58.229 Class Phalcon\Translate\Adapter\NativeArray

extends abstract class Phalcon\Translate\Adapter

implements Phalcon\Translate\AdapterInterface, ArrayAccess

Allows to define translation lists using PHP arrays

Methods

`public __construct (unknown $options)`

Phalcon\Translate\Adapter\NativeArray constructor

`public string query (unknown $index, [unknown $placeholders])`

Returns the translation related to the given key

`public bool exists (unknown $index)`

Check whether is defined a translation key in the internal array

`public string t (unknown $translateKey, [unknown $placeholders])` inherited from Phalcon\Translate\Adapter

Returns the translation string of the given key

`public string _ (unknown $translateKey, [unknown $placeholders])` inherited from Phalcon\Translate\Adapter

Returns the translation string of the given key (alias of method ‘t’)

`public offsetSet (unknown $offset, unknown $value)` inherited from Phalcon\Translate\Adapter

Sets a translation value

`public boolean offsetExists (unknown $translateKey)` inherited from Phalcon\Translate\Adapter

Check whether a translation key exists

public **offsetUnset** (*unknown \$offset*) inherited from Phalcon\Translate\Adapter

Unsets a translation from the dictionary

public *string* **offsetGet** (*unknown \$translateKey*) inherited from Phalcon\Translate\Adapter

Returns the translation related to the given key

2.58.230 Class Phalcon\Translate\Exception

extends class Phalcon\Exception

Methods

final private *Exception* **__clone** () inherited from Exception

Clone the exception

public **__construct** ([*string \$message*], [*int \$code*], [*Exception \$previous*]) inherited from Exception

Exception constructor

final public *string* **getMessage** () inherited from Exception

Gets the Exception message

final public *int* **getCode** () inherited from Exception

Gets the Exception code

final public *string* **getFile** () inherited from Exception

Gets the file in which the exception occurred

final public *int* **getLine** () inherited from Exception

Gets the line in which the exception occurred

final public *array* **getTrace** () inherited from Exception

Gets the stack trace

final public *Exception* **getPrevious** () inherited from Exception

Returns previous Exception

final public *Exception* **getTraceAsString** () inherited from Exception

Gets the stack trace as a string

public *string* **__toString** () inherited from Exception

String representation of the exception

2.58.231 Class Phalcon\Validation

extends abstract class Phalcon\Di\Injectable

implements Phalcon\Events\EventsAwareInterface, Phalcon\Di\InjectionAwareInterface

Allows to validate data using custom or built-in validators

Methods

public **setValidators** (*unknown* \$validators)

...

public **__construct** ([*unknown* \$validators])

Phalcon\Validation constructor

public [Phalcon\Validation\Message\Group validate](#) ([*unknown* \$data], [*unknown* \$entity])

Validate a set of data according to a set of rules

public [Phalcon\Validation add](#) (*unknown* \$field, *unknown* \$validator)

Adds a validator to a field

public [Phalcon\Validation rule](#) (*unknown* \$field, *unknown* \$validator)

Alias of *add* method

public [Phalcon\Validation rules](#) (*unknown* \$field, *unknown* \$validators)

Adds the validators to a field

public [Phalcon\Validation setFilters](#) (*unknown* \$field, *unknown* \$filters)

Adds filters to the field

public *mixed* [getFilters](#) ([*unknown* \$field])

Returns all the filters or a specific one

public *array* [getValidators](#) ()

Returns the validators added to the validation

public *object* [getEntity](#) ()

Returns the bound entity

public *array* [setDefaultMessages](#) ([*unknown* \$messages])

Adds default messages to validators

public *string* [getDefaultMessage](#) (*unknown* \$type)

Get default message for validator type

public [Phalcon\Validation\Message\Group getMessages](#) ()

Returns the registered validators

public **setLabels** (*unknown* \$labels)

Adds labels for fields

public *string* [getLabel](#) (*unknown* \$field)

Get label for field

public [Phalcon\Validation appendMessage](#) (*unknown* \$message)

Appends a message to the messages list

public [Phalcon\Validation bind](#) (*unknown* \$entity, *unknown* \$data)

Assigns the data to an entity The entity is used to obtain the validation values

public *mixed* [getValue](#) (*unknown* \$field)

Gets the a value to validate in the array/object data source

public `setDI` (*unknown* \$dependencyInjector) inherited from Phalcon\Di\Injectable

Sets the dependency injector

public `Phalcon\DiInterface getDI` () inherited from Phalcon\Di\Injectable

Returns the internal dependency injector

public `setEventsManager` (*unknown* \$eventsManager) inherited from Phalcon\Di\Injectable

Sets the event manager

public `Phalcon\Events\ManagerInterface getEventsManager` () inherited from Phalcon\Di\Injectable

Returns the internal event manager

public `__get` (*unknown* \$propertyName) inherited from Phalcon\Di\Injectable

Magic method `__get`

2.58.232 Class Phalcon\Validation\Exception

extends class Phalcon\Exception

Methods

final private `Exception __clone` () inherited from Exception

Clone the exception

public `__construct` ([*string* \$message], [*int* \$code], [*Exception* \$previous]) inherited from Exception

Exception constructor

final public `string getMessage` () inherited from Exception

Gets the Exception message

final public `int getCode` () inherited from Exception

Gets the Exception code

final public `string getFile` () inherited from Exception

Gets the file in which the exception occurred

final public `int getLine` () inherited from Exception

Gets the line in which the exception occurred

final public `array getTrace` () inherited from Exception

Gets the stack trace

final public `Exception getPrevious` () inherited from Exception

Returns previous Exception

final public `Exception getTraceAsString` () inherited from Exception

Gets the stack trace as a string

public `string __toString` () inherited from Exception

String representation of the exception

2.58.233 Class Phalcon\Validation\Message

implements Phalcon\Validation\MessageInterface

Encapsulates validation info generated in the validation process

Methods

public __construct (*unknown* \$message, [*unknown* \$field], [*unknown* \$type])

Phalcon\Validation\Message constructor

public Phalcon\Validation\Message setType (*unknown* \$type)

Sets message type

public string getType ()

Returns message type

public Phalcon\Validation\Message setMessage (*unknown* \$message)

Sets verbose message

public string getMessage ()

Returns verbose message

public Phalcon\Validation\Message setField (*unknown* \$field)

Sets field name related to message

public string getField ()

Returns field name related to message

public string __toString ()

Magic __toString method returns verbose message

public static Phalcon\Validation\Message __set_state (*unknown* \$message)

Magic __set_state helps to recover messages from serialization

2.58.234 Class Phalcon\Validation\Message\Group

implements Countable, ArrayAccess, Iterator, Traversable

Represents a group of validation messages

Methods

public __construct ([*unknown* \$messages])

Phalcon\Validation\Message\Group constructor

public Phalcon\Validation\Message offsetGet (*unknown* \$index)

Gets an attribute a message using the array syntax

```
<?php  
print_r($messages[0]);
```

public offsetSet (unknown \$index, unknown \$message)

Sets an attribute using the array-syntax

```
<?php
$messages[0] = new \Phalcon\Validation\Message('This is a message');
```

public boolean offsetExists (unknown \$index)

Checks if an index exists

```
<?php
var_dump(isset($message['database']));
```

public offsetUnset (unknown \$index)

Removes a message from the list

```
<?php
unset($message['database']);
```

public appendMessage (unknown \$message)

Appends a message to the group

```
<?php
$messages->appendMessage(new \Phalcon\Validation\Message('This is a message'));
```

public appendMessages (unknown \$messages)

Appends an array of messages to the group

```
<?php
$messages->appendMessages($messagesArray);
```

public array filter (unknown \$fieldName)

Filters the message group by field name

public int count ()

Returns the number of messages in the list

public rewind ()

Rewinds the internal iterator

public Phalcon\Validation\Message current ()

Returns the current message in the iterator

public int key ()

Returns the current position/key in the iterator

public next ()

Moves the internal iteration pointer to the next position

public boolean valid ()

Check if the current message in the iterator is valid

public static Phalcon\Validation\Message\Group **__set_state** (*unknown* \$group)

Magic __set_state helps to re-build messages variable when exporting

2.58.235 Class Phalcon\Validation\Validator

This is a base class for validators

Methods

public **__construct** ([*unknown* \$options])

Phalcon\Validation\Validator constructor

public *boolean* **isSetOption** (*unknown* \$key)

Checks if an option is defined

public *mixed* **getOption** (*unknown* \$key)

Returns an option in the validator's options Returns null if the option hasn't set

public **setOption** (*unknown* \$key, *unknown* \$value)

Sets an option in the validator

2.58.236 Class Phalcon\Validation\Validator\Alnum

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Check for alphanumeric character(s)

```
<?php

use Phalcon\Validation\Validator\Alnum as AlnumValidator;

$validator->add('username', new AlnumValidator(array(
    'message' => ':field must contain only alphanumeric characters'
)));
```

Methods

public *boolean* **validate** (*unknown* \$validation, *unknown* \$field)

Executes the validation

public **__construct** ([*unknown* \$options]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

public *boolean* **isSetOption** (*unknown* \$key) inherited from Phalcon\Validation\Validator

Checks if an option is defined

public *mixed* **getOption** (*unknown* \$key) inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

public `setOption` (*unknown \$key, unknown \$value*) inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.237 Class Phalcon\Validation\Validator\Alpha

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Check for alphabetic character(s)

```
<?php

use Phalcon\Validation\Validator\Alpha as AlphaValidator;

$validator->add('username', new AlphaValidator(array(
    'message' => ':field must contain only letters'
)) );
```

Methods

public boolean validate (*unknown \$validation, unknown \$field*)

Executes the validation

public __construct ([*unknown \$options*]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

public boolean isSetOption (*unknown \$key*) inherited from Phalcon\Validation\Validator

Checks if an option is defined

public mixed getOption (*unknown \$key*) inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

public `setOption` (*unknown \$key, unknown \$value*) inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.238 Class Phalcon\Validation\Validator\Between

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Validates that a value is between an inclusive range of two values. For a value x, the test is passed if minimum<=x<=maximum.

```
<?php

use Phalcon\Validation\Validator\Between;

validator->add('name', new Between(array(
    'minimum' => 0,
    'maximum' => 100,
    'message' => 'The price must be between 0 and 100'
)) );
```

Methods

public boolean validate (*unknown \$validation, unknown \$field*)

Executes the validation

public __construct ([*unknown \$options*]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

public boolean isSetOption (*unknown \$key*) inherited from Phalcon\Validation\Validator

Checks if an option is defined

public mixed getOption (*unknown \$key*) inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

public setOption (*unknown \$key, unknown \$value*) inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.239 Class Phalcon\Validation\Validator\Confirmation

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Checks that two values have the same value

```
<?php

use Phalcon\Validation\Validator\Confirmation;

$validator->add('password', new Confirmation(array(
    'message' => 'Password doesn\'t match confirmation',
    'with' => 'confirmPassword'
)) );
```

Methods

public boolean validate (*unknown \$validation, unknown \$field*)

Executes the validation

public __construct ([*unknown \$options*]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

public boolean isSetOption (*unknown \$key*) inherited from Phalcon\Validation\Validator

Checks if an option is defined

public mixed getOption (*unknown \$key*) inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

public setOption (*unknown \$key, unknown \$value*) inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.240 Class Phalcon\Validation\Validator\Digit

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Check for numeric character(s)

```
<?php

use Phalcon\Validation\Validator\Digit as DigitValidator;

$validator->add('height', new DigitValidator(array(
    'message' => ':field must be numeric'
)) );
```

Methods

public *boolean* validate (*unknown* \$validation, *unknown* \$field)

Executes the validation

public __construct ([*unknown* \$options]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

public *boolean* isSetOption (*unknown* \$key) inherited from Phalcon\Validation\Validator

Checks if an option is defined

public *mixed* getOption (*unknown* \$key) inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

public *setOption* (*unknown* \$key, *unknown* \$value) inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.241 Class Phalcon\Validation\Validator>Email

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Checks if a value has a correct e-mail format

```
<?php

use Phalcon\Validation\Validator\Email as EmailValidator;

$validator->add('email', new EmailValidator(array(
    'message' => 'The e-mail is not valid'
)) );
```

Methods

public *boolean* validate (*unknown* \$validation, *unknown* \$field)

Executes the validation

public **__construct** ([*unknown \$options*]) inherited from Phalcon\Validation\Validator
Phalcon\Validation\Validator constructor

public **boolean isSetOption** (*unknown \$key*) inherited from Phalcon\Validation\Validator
Checks if an option is defined

public **mixed getOption** (*unknown \$key*) inherited from Phalcon\Validation\Validator
Returns an option in the validator's options Returns null if the option hasn't set

public **setOption** (*unknown \$key*, *unknown \$value*) inherited from Phalcon\Validation\Validator
Sets an option in the validator

2.58.242 Class Phalcon\Validation\Validator\ExclusionIn

extends class Phalcon\Validation\Validator
implements Phalcon\Validation\ValidatorInterface
Check if a value is not included into a list of values

```
<?php

use Phalcon\Validation\Validator\ExclusionIn;

$validator->add('status', new ExclusionIn(array(
    'message' => 'The status must not be A or B',
    'domain' => array('A', 'B')
)) );
```

Methods

public **boolean validate** (*unknown \$validation*, *unknown \$field*)
Executes the validation

public **__construct** ([*unknown \$options*]) inherited from Phalcon\Validation\Validator
Phalcon\Validation\Validator constructor

public **boolean isSetOption** (*unknown \$key*) inherited from Phalcon\Validation\Validator
Checks if an option is defined

public **mixed getOption** (*unknown \$key*) inherited from Phalcon\Validation\Validator
Returns an option in the validator's options Returns null if the option hasn't set

public **setOption** (*unknown \$key*, *unknown \$value*) inherited from Phalcon\Validation\Validator
Sets an option in the validator

2.58.243 Class Phalcon\Validation\Validator\File

extends class Phalcon\Validation\Validator
implements Phalcon\Validation\ValidatorInterface
Checks if a value has a correct file

```
<?php

use Phalcon\Validation\Validator\File as FileValidator;

$validator->add('file', new FileValidator(array(
    'maxSize' => '2M',
    'messageSize' => ':field exceeds the max filesize (:max)',
    'allowedTypes' => array('image/jpeg', 'image/png'),
    'messageType' => 'Allowed file types are :types',
    'maxResolution' => '800x600',
    'messageMaxResolution' => 'Max resolution of :field is :max'
)));

```

Methods

public boolean validate (*unknown* \$validation, *unknown* \$field)

Executes the validation

public __construct ([*unknown* \$options]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

public boolean isSetOption (*unknown* \$key) inherited from Phalcon\Validation\Validator

Checks if an option is defined

public mixed getOption (*unknown* \$key) inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

public setOption (*unknown* \$key, *unknown* \$value) inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.244 Class Phalcon\Validation\Validator\Identical

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Checks if a value is identical to other

```
<?php

use Phalcon\Validation\Validator\Identical;

$validator->add('terms', new Identical(array(
    'accepted' => 'yes',
    'message' => 'Terms and conditions must be accepted'
)));

```

Methods

public boolean validate (*unknown* \$validation, *unknown* \$field)

Executes the validation

public __construct ([*unknown* \$options]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

`public boolean isSetOption (unknown $key)` inherited from Phalcon\Validation\Validator

Checks if an option is defined

`public mixed getOption (unknown $key)` inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

`public setOption (unknown $key, unknown $value)` inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.245 Class Phalcon\Validation\Validator\InclusionIn

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Check if a value is included into a list of values

```
<?php

use Phalcon\Validation\Validator\InclusionIn;

$validator->add('status', new InclusionIn(array(
    'message' => 'The status must be A or B',
    'domain' => array('A', 'B')
)) );
```

Methods

`public boolean validate (unknown $validation, unknown $field)`

Executes the validation

`public __construct ([unknown $options])` inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

`public boolean isSetOption (unknown $key)` inherited from Phalcon\Validation\Validator

Checks if an option is defined

`public mixed getOption (unknown $key)` inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

`public setOption (unknown $key, unknown $value)` inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.246 Class Phalcon\Validation\Validator\Numericality

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Check for a valid numeric value

```
<?php

use Phalcon\Validation\Validator\Numericality;

$validator->add('price', new Numericality(array(
    'message' => ':field is not numeric'
)) );
```

Methods

public boolean validate (unknown \$validation, unknown \$field)

Executes the validation

public __construct ([unknown \$options]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

public boolean isSetOption (unknown \$key) inherited from Phalcon\Validation\Validator

Checks if an option is defined

public mixed getOption (unknown \$key) inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

public setOption (unknown \$key, unknown \$value) inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.247 Class Phalcon\Validation\Validator\PresenceOf

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Validates that a value is not null or empty string

```
<?php

use Phalcon\Validation\Validator\PresenceOf;

$validator->add('name', new PresenceOf(array(
    'message' => 'The name is required'
)) );
```

Methods

public boolean validate (unknown \$validation, unknown \$field)

Executes the validation

public __construct ([unknown \$options]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

public boolean isSetOption (unknown \$key) inherited from Phalcon\Validation\Validator

Checks if an option is defined

public mixed getOption (unknown \$key) inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

public **setOption** (*unknown* \$key, *unknown* \$value) inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.248 Class Phalcon\Validation\Validator\Regex

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Allows validate if the value of a field matches a regular expression

```
<?php

use Phalcon\Validation\Validator\Regex as RegexValidator;

$validator->add('created_at', new RegexValidator(array(
    'pattern' => '/^([0-9]{4})[-/](0[1-9]|1[0-2])[-/](0[1-9]|1[0-2])[0-9]|3[01])$/',
    'message' => 'The creation date is invalid'
));
```

Methods

public *boolean* **validate** (*unknown* \$validation, *unknown* \$field)

Executes the validation

public **__construct** ([*unknown* \$options]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

public *boolean* **isSetOption** (*unknown* \$key) inherited from Phalcon\Validation\Validator

Checks if an option is defined

public *mixed* **getOption** (*unknown* \$key) inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

public **setOption** (*unknown* \$key, *unknown* \$value) inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.249 Class Phalcon\Validation\Validator\StringLength

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Validates that a string has the specified maximum and minimum constraints The test is passed if for a string's length L, $\text{min} \leq L \leq \text{max}$, i.e. L must be at least min, and at most max.

```
<?php

use Phalcon\Validation\Validator\StringLength as StringLength;

$validation->add('name_last', new StringLength(array(
    'max' => 50,
```

```

    'min' => 2,
    'messageMaximum' => 'We don\'t like really long names',
    'messageMinimum' => 'We want more than just their initials'
));

```

Methods

public boolean validate (*unknown* \$validation, *unknown* \$field)

Executes the validation

public __construct ([*unknown* \$options]) inherited from Phalcon\Validation\Validator

Phalcon\Validation\Validator constructor

public boolean isSetOption (*unknown* \$key) inherited from Phalcon\Validation\Validator

Checks if an option is defined

public mixed getOption (*unknown* \$key) inherited from Phalcon\Validation\Validator

Returns an option in the validator's options Returns null if the option hasn't set

public setOption (*unknown* \$key, *unknown* \$value) inherited from Phalcon\Validation\Validator

Sets an option in the validator

2.58.250 Class Phalcon\Validation\Validator\Uniqueness

extends class Phalcon\Validation\Validator

implements Phalcon\Validation\ValidatorInterface

Check that a field is unique in the related table

```

<?php

use Phalcon\Validation\Validator\Uniqueness as UniquenessValidator;

$validator->add('username', new UniquenessValidator(array(
    'model' => 'Users',
    'message' => ':field must be unique'
)));

```

Different attribute from the field

```

<?php

$validator->add('username', new UniquenessValidator(array(
    'model' => 'Users',
    'attribute' => 'nick'
)));

```

Methods

public boolean validate (*unknown* \$validation, *unknown* \$field)

Executes the validation

public **__construct** ([*unknown \$options*]) inherited from Phalcon\Validation\Validator
Phalcon\Validation\Validator constructor

public **boolean isSetOption** (*unknown \$key*) inherited from Phalcon\Validation\Validator
Checks if an option is defined

public **mixed getOption** (*unknown \$key*) inherited from Phalcon\Validation\Validator
Returns an option in the validator's options Returns null if the option hasn't set

public **setOption** (*unknown \$key*, *unknown \$value*) inherited from Phalcon\Validation\Validator
Sets an option in the validator

2.58.251 Class Phalcon\Validation\Validator\Url

extends class Phalcon\Validation\Validator
implements Phalcon\Validation\ValidatorInterface
Checks if a value has a url format

```
<?php

use Phalcon\Validation\Validator\Url as UrlValidator;

$validator->add('url', new UrlValidator(array(
    'message' => ':field must be a url'
)) );
```

Methods

public **boolean validate** (*unknown \$validation*, *unknown \$field*)
Executes the validation

public **__construct** ([*unknown \$options*]) inherited from Phalcon\Validation\Validator
Phalcon\Validation\Validator constructor

public **boolean isSetOption** (*unknown \$key*) inherited from Phalcon\Validation\Validator
Checks if an option is defined

public **mixed getOption** (*unknown \$key*) inherited from Phalcon\Validation\Validator
Returns an option in the validator's options Returns null if the option hasn't set

public **setOption** (*unknown \$key*, *unknown \$value*) inherited from Phalcon\Validation\Validator
Sets an option in the validator

2.58.252 Class Phalcon\Version

This class allows to get the installed version of the framework

Constants

integer **VERSION_MAJOR**
integer **VERSION_MEDIUM**
integer **VERSION_MINOR**
integer **VERSION_SPECIAL**
integer **VERSION_SPECIAL_NUMBER**

Methods

protected static *string* **_getVersion ()**

Area where the version number is set. The format is as follows: ABBCCDE A - Major version B - Med version (two digits) C - Min version (two digits) D - Special release: 1 = Alpha, 2 = Beta, 3 = RC, 4 = Stable E - Special release version i.e. RC1, Beta2 etc.

final protected static *string* **_getSpecial (unknown \$special)**

Translates a number to a special release If Special release = 1 this function will return ALPHA

public static *string* **get ()**

Returns the active version (string)

```
<?php
echo Phalcon\Version::get();
```

public static *string* **getId ()**

Returns the numeric active version

```
<?php
echo Phalcon\Version::getId();
```

public static *string* **getPart (unknown \$part)**

Returns a specific part of the version. If the wrong parameter is passed it will return the full version

```
<?php
echo Phalcon\Version::getPart (Phalcon\Version::VERSION_MAJOR);
```

2.58.253 Interface Phalcon\Acl\AdapterInterface

Methods

abstract public **setDefaultAction (unknown \$defaultAccess)**

...

abstract public **getDefaultAction ()**

...

abstract public **addRole (unknown \$role, [unknown \$accessInherits])**

```
...
abstract public addInherit (unknown $roleName, unknown $roleToInherit)
...
abstract public isRole (unknown $roleName)
...
abstract public isResource (unknown $resourceName)
...
abstract public addResource (unknown $resourceObject, [unknown $accessList])
...
abstract public addResourceAccess (unknown $resourceName, unknown $accessList)
...
abstract public dropResourceAccess (unknown $resourceName, unknown $accessList)
...
abstract public allow (unknown $roleName, unknown $resourceName, unknown $access)
...
abstract public deny (unknown $roleName, unknown $resourceName, unknown $access)
...
abstract public isAllowed (unknown $roleName, unknown $resourceName, unknown $access)
...
abstract public getActiveRole ()
...
abstract public getActiveResource ()
...
abstract public getActiveAccess ()
...
abstract public getRoles ()
...
abstract public getResources ()
...
```

2.58.254 Interface Phalcon\Acl\ResourceInterface

Methods

```
abstract public __construct (unknown $name, [unknown $description])
...
abstract public getName ()
```

```
...
abstract public getDescription ()

...
abstract public _toString ()

...
```

2.58.255 Interface Phalcon\Acl\RoleInterface

Methods

```
abstract public __construct (unknown $name, [unknown $description])

...
abstract public getName ()

...
abstract public getDescription ()

...
abstract public _toString ()

...
```

2.58.256 Interface Phalcon\Annotations\AdapterInterface

Methods

```
abstract public setReader (unknown $reader)

...
abstract public getReader ()

...
abstract public get (unknown $className)

...
abstract public getMethods (unknown $className)

...
abstract public getMethod (unknown $className, unknown $methodName)

...
abstract public getProperties (unknown $className)

...
abstract public getProperty (unknown $className, unknown $propertyName)

...
```

2.58.257 Interface Phalcon\Annotations\ReaderInterface

Methods

```
abstract public parse (unknown $className)  
...  
abstract public static parseDocBlock (unknown $docBlock, [unknown $file], [unknown $line])  
...
```

2.58.258 Interface Phalcon\Assets\FilterInterface

Methods

```
abstract public filter (unknown $content)  
...
```

2.58.259 Interface Phalcon\Cache\BackendInterface

Methods

```
abstract public start (unknown $keyName, [unknown $lifetime])  
...  
abstract public stop ([unknown $stopBuffer])  
...  
abstract public getFrontend ()  
...  
abstract public getOptions ()  
...  
abstract public isFresh ()  
...  
abstract public isStarted ()  
...  
abstract public setLastKey (unknown $lastKey)  
...  
abstract public getLastKey ()  
...  
abstract public get (unknown $keyName, [unknown $lifetime])  
...  
abstract public save ([unknown $keyName], [unknown $content], [unknown $lifetime], [unknown $stopBuffer])  
...
```

```
abstract public delete (unknown $keyName)  
...  
abstract public queryKeys ([unknown $prefix])  
...  
abstract public exists ([unknown $keyName], [unknown $lifetime])  
...
```

2.58.260 Interface Phalcon\Cache\FrontendInterface

Methods

```
abstract public getLifetime ()  
...  
abstract public isBuffering ()  
...  
abstract public start ()  
...  
abstract public getContent ()  
...  
abstract public stop ()  
...  
abstract public beforeStore (unknown $data)  
...  
abstract public afterRetrieve (unknown $data)  
...
```

2.58.261 Interface Phalcon\CryptInterface

Methods

```
abstract public setCipher (unknown $cipher)  
...  
abstract public getCipher ()  
...  
abstract public setMode (unknown $mode)  
...  
abstract public getMode ()  
...  
abstract public setKey (unknown $key)
```

```
...
